HEMANGIOMAS OF THE SKIN

GRANT E. WARD, M.D.

AND

E. EUGENE COVINGTON, M.D.

BALTIMORE

Our object in this paper is to record our observations and results of present day methods of therapy in the treatment of ninety-four consecutive cases of superficial hemangiomas representing 127 lesions. All of the material used for this paper is from the Oncology Clinic of the University of Maryland School of Medicine and Hospital. This work covers an eight year period, i. e. from the opening of the Oncology Clinic in the fall of the year 1930 to the end of the year 1938.

In a study of several hundred papers in recent current medical literature dealing with hemangiomas, we found that few authors gave details of therapeutic techniques and actual statistics of results. Here we report carefully prepared statistics and show that even though radium irradiation usually gives the best results of any form of therapy, there have been times when the cosmetic results were not entirely satisfactory. This percentage of unsatisfactory cosmetic results is small and may be present with any form of treatment. It is to be recalled that surgical excision is not without scarring, the amount of surgical scar varying, of course, with the skill of the operator and the amount of tumor removed. When large hemangiomas are excised, some tension is put on the skin edges with a resultant wide scar. Large hemangiomas may also require two stage operations for complete excision. In considering cosmetic results one must give an honest evaluation of all forms of therapy as related to the resulting scar in comparison with the original size of the lesion and the disfigurement.

INCIDENCE AND LOCATION

The most frequent location for superficial hemangioma is the nape of the neck. This is the commonly seen naevus simplex or telangiectasia nuchae of newborn babies. According to Blaisdell¹ a careful routine physical examination will show this type present in about 33 per cent of all newborn babies of the white race. We have not noticed this condition so frequently, but there is no doubt that it is common. These lesions usually are small and patchy in distribution, disappear easily on pressure, are never elevated, are pale red, and therefore do not impress the average observer as hemangiomas. A routine physical examination of adults often shows these reddened areas about the hairline of the neck even though the person was never aware of the

mark. As a result no treatment is necessary, and such hemangiomas will not be considered further in this paper.

The second most common location for superficial hemangiomas is the head. In this series of 127 hemangiomas the lesions were found on various parts of the head in the following order of frequency: face 28.2 per cent, scalp 11 per cent, lip 11.8 per cent, neck 3.9 per cent (exclusive of telangiectasia nuchae) and eyelid 2.3 per cent; therefore a total of 57.2 per cent of all hemangiomas were about the head. The face was also the most frequently selected site for port wine stains (naevus flammeus), which occurred in 5.3 per cent of this series. This is unfortunate, for such hemangiomas give the poorest results with any form of therapy.

Hemangiomas appeared on the body and extremities as follows: chest 7.1 per cent, extremities 15.7 per cent, abdomen 3.9 per cent, back 12.6 per cent, vulva 1.5 per cent, scrotum 8 per cent, buccal mucosa 8 per cent.

We record here the twentieth case of hemangioma of the scrotum. It was a typical hemangioma, 0.5 cm. in diameter and elevated 0.2 mm., it disappeared easily on pressure, and it was not associated with the underlying contents of the scrotum. The nineteenth was reported by Gibson,² who brought the literature to date. Our patient was treated successfully by solid carbon dioxide.

In 55 per cent of the cases the hemangioma was single, but in 45 per cent there were two or more, a rather high percentage of multiple lesions. The association of superficial hemangioma with hemangioma in some internal organ has been reported many times, especially in pediatric and neurologic literature, the most common association being hemangioma of the face with hemangioma of the brain. Our series does not agree with the literature in this regard.

CLINICAL CHARACTERISTICS

Three fourths of the superficial hemangiomas were present at birth, but an appreciable number did not appear until one or two months later. Hemangiomas seldom develop in infants after the first year, and thereafter the frequency decreases with age. It is unusual to see a hemangioma begin in an adult. The port wine stains were all present at birth.

Port wine stains usually remain of the same size and intensity of color noticed at birth except that they grow as the child grows, but there are a certain number of the cavernous and capillary hemangiomas which will increase in size and become more pronounced in color. Three cases of hemangioma of the extremities in this series enlarged after birth. The importance of this increase in size after birth is to be emphasized, as early

treatment may prevent this growth. Only one case in this series extended laterally after radium treatment (fig. 6A).

In the present series 90 per cent of the hemangiomas were in the white race and 10 per cent in the Negro race; 35 per cent were in males and 65 per cent in females. We believe that more blonds have hemangiomas than brunets, although we have found no statistics in the literature to substantiate this observation.

TREATMENT

Optimal Age.—Treatment should be instituted as early as possible. It is better to begin before the child is 3 months old, but certainly before the end of the first year. Early treatment is recommended mainly for three reasons: 1. The endothelial cells lining the vascular spaces of the tumor are more radiosensitive during their embryonic and early life. The radiosensitivity of these cells decreases in direct proportion to age; therefore the good results from irradiation decrease in the same proportion. Our observations correspond with those of Figi,³ who had poor results with irradiation of hemangiomas about the face in young adults. He advocates either electrocoagulation or surgical excision with skin grafting when necessary for these failures of radiation therapy. 2. Early treatment will prevent most lesions from getting larger and spreading laterally. 3. Residual effects of irradiation, such as scarring and increased pigmentation, decrease as the years go on, making for better cosmetic results. The earlier the treatment, then, the earlier and better the result.

Radium Technic.—In our clinic new cases are seen by a surgeon and a radiologist to get an unbiased opinion of the proper therapy. More lesions were treated by external irradiation than any other method. Radium alone was used in 74 per cent of cases and roentgen therapy alone, or more often combined with radium, in 10 per cent. Our technic for radium therapy is as follows: The amount of radium is usually 100 mg. of radium element, the filter is 1 mm. of platinum, screened with aluminum foil and rubber or felt, the distance

plaque is made to suit the size and shape of the tumor, permitting the radiation to be equally distributed throughout the growth.⁴ The same treatment is repeated every three or four months until the growth disappears. Large hemangiomas have to be marked off into several areas corresponding to the size of the radium plaque used, and each area is treated separately, overlapping being guarded against.

Fig. 2.—A typical hemangioma of the face, A before and B after radium treatment. No other form of therapy would give such a pretty cosmetic result.

The greatest effect from the irradiation will be seen within the first two months, followed by a slow but progressive fading for from four to six months. This slowness of effect is important to remember and, if kept in mind, will often prevent overirradiation. We prefer the minimum number of treatments which will give the optimum result, for the less irradiation used the less likely is sclerosis, atrophy, increased pigmentation or other abnormality to be left as a residual effect of overirradiation. One treatment was sufficient for 31.5 per cent of the 127 hemangiomas, but two and even three treatments were necessary for the remainder. Infants required fewer treatments than older children. With our technic of the radium element plaque, it is unwise to use more than two or three treatments to any one area because of the danger of late residual effects. When three such treatments fail to obliterate the growth with a good cosmetic result, some other procedure, usually excision, is used. Newcomet,⁵ of Philadelphia, and many others emphasized that small doses of radium, especially in the beginning of treatment, repeated several times over a long period, give the best cosmetic results of any type of hemangioma therapy. In the future we intend to use smaller doses than those outlined, as experience has taught us that the reaction is often too pronounced. Slightly smaller doses, i. e. from 175 to 200 milligram hours, repeated three or four times, will probably cause less reaction with just as much disappearance of the lesion.

Irradiation, either by radium or roentgen rays, acts by producing obliterative endarteritis and a mild diffuse sclerosis of the surrounding stroma. The ultimate results depend on at least three factors: radiosensitivity of the tumor cells, size of the vascular spaces, and asso-

Fig. 1.—A typical good result of radium, A before and B after treatment. No other form of therapy could equal this cosmetic result.

usually one-fourth inch (0.6 cm.), the time from two to two and one-half hours; therefore the dose is from 200 to 250 milligram hours. The platinum filter will remove all the caustic beta rays, and the aluminum foil and rubber will remove most of the secondary rays from the primary filter. This combination filter gives a shorter and more uniform wavelength. The radium

4. This dose over an area from 1 to 1½ inches in diameter usually produces an erythema in blonds and a suberythema in brunets in about seven to ten days. The University of Maryland Hospital has available 230 mg. of radium element distributed in tubes of 10 and 20 mg. strength, each with 1 mm. of platinum, and nineteen needles of 2, 5 and 10 mg. strength, each with a 0.5 mm. platinum filter.

ciated proliferation of connective tissue stroma. Each will be discussed separately.

Radiosensitivity.—By radiosensitivity is meant the amount and speed of response of tissues to the application of radium or roentgen rays. It is a complex biologic phenomenon depending on several factors, two of which every one has agreed on: (1) the radiosensitivity of the tumor cells and (2) the radiosensitivity of the surrounding stroma.

1. According to Cutler, Buschke and Cantril,⁶ the radiosensitivity of tumor cells is separated into three forms: (a) inherent, (b) transient and (c) acquired.

(a) Every cell has a certain characteristic inherent radiosensitivity. We do not know much about this intracellular reaction but it is believed to be determined by the usual life history of the cell. Blood cells, especially lymphocytes, have a short duration of life; mesodermal cells, such as those of muscle, connective tissue or bone, have a longer duration of life, and nerve cells have the longest duration of life of any cells in the body. It is therefore easy to see that tumors developing from lymphatic tissue, i.e. in lymphosarcoma and Hodgkin's disease, are the most sensitive of all tumors to irradiation, while tumors developing from nerve cell origin, i.e. neuroma and neurogenic sarcoma, are the most resistant to irradiation. Lymphocytes are then the most radiosensitive cells, ovarian and testicular cells rank second, and hemangiomas probably about third. A hemangioma, then, is fairly sensitive to irradiation.

(b) By transient radiosensitivity is meant the cellular response during certain phases of the cell's life history. A cell is most radiosensitive during mitosis and this radiosensitivity decreases as the cell grows older.

(c) By acquired radiosensitivity is meant the alteration in the original, or inherent, radiosensitivity. Radiosensitivity is never increased during the life of a cell but it may be decreased by several factors, the most important of which is diminished blood supply. One way in which this may be brought about is by previous irradiation, which causes obliterative endarteritis and

hemangiomas but applies particularly to sarcomas and epitheliomas. The age of the individual is an important factor in determining acquired radiosensitivity, this being especially true with hemangiomas and to a lesser extent with sarcomas and epitheliomas. A hemangioma is most radiosensitive during the early months of life. The radiosensitivity decreases in direct proportion to the age of the individual. Radiosensitivity of heman-

Fig. 4.—Papillomatous type of hemangioma of the scalp, A before and B immediately after treatment by electrodesiccation, showing a typical good result of electrodesiccation when the tumor has a narrow base. The dark spot in B is gentian violet applied to the desiccated area to show the amount of scar.

gioma is low in older children (over 3 or 4 years) and in adults hemangiomas are radioresistant.

2. The second known factor about radiosensitivity is the response of the stroma to irradiation. The tissues which make up the stroma supporting the tumor are mesodermal in origin, consisting of connective tissue, muscle, blood vessels and bone. The cells of these tissues, with the exception of blood vessels, are more radioresistant than the cells of hemangioma, epithelioma or even sarcoma, except neurogenic sarcoma. An epidermoid carcinoma developing in the region of the pharynx or tonsil is more radiosensitive than the same tumor histologically developing from the lip or growing as a metastasis in bone. In each case the surrounding stroma is different. The pharyngeal wall contains much lymphatic tissue, which is radiosensitive, the lip is made up of less radiosensitive muscle and connective tissue, and bone is still less radiosensitive. This is true to a lesser degree in hemangioma. A hemangioma beginning on the skin certainly seems more radiosensitive than the growth located in subcutaneous tissues, muscles or bone.

We have noted that hemangiomas containing large amounts of fat and connective tissue, which are firm and do not flatten out on pressure, also do not entirely disappear following irradiation. This is to be expected, as fat and connective tissue are resistant to the action of gamma rays of radium or roentgen rays. The vascular spaces become sclerosed, as evidenced by the change in color and partial reduction in size, and there is improvement but never a complete cure. Fortunately this mixed type of hemangioma is uncommon. It might be well to consider surgical excision at the outset of treatment in such cases provided the lesion is located on a site where excision is easily carried out.

The ultimate results of irradiation also depend on the size of the vascular spaces making up the tumor. A capillary hemangioma is a mass of small embryonic blood spaces with a supporting stroma. This is the usual type found in the skin; it may or may not be elevated, does not pulsate, usually blanches easily on

Fig. 3.—Hemangioma, A before and B after radium therapy. Severe infection followed treatment and trauma caused by scratching. Note involvement of eyelids and lips, a problem difficult or impossible to handle by plastic surgery. Marked scarring and residual patches of hemangioma remain. This is a bad result, but no other form of therapy would do as well. Solid carbon dioxide and electrodesiccation are to be used on the remaining patches of hemangioma. Much of this scar will soften with age.

a mild diffuse sclerosis, thus reducing the blood supply. Each course of irradiation makes a tumor more and more radioresistant. This is true to a certain extent of

6. Cutler, Max; Buschke, Franz, and Cantril, S. T.: *Cancer: Its Diagnosis and Treatment*, Philadelphia, W. B. Saunders Company, 1938, pp. 1-5.

pressure and is the most radiosensitive of all hemangiomas. The only difference between a capillary and a cavernous hemangioma is the size of the vascular spaces composing the tumor. A cavernous hemangioma, especially a large one, usually has one or more afferent and efferent vessels. These tumors often pulsate. Most large hemangiomas, subcutaneous hemangiomas and hemangiomas originating in internal organs, i. e. in the liver, spleen, tongue and muscle, are cavernous in type. Cavernous hemangiomas, as a general rule, do not respond quite as well to irradiation as the capillary group. Our explanation for the lesser effect of irradiation on cavernous hemangiomas is that the vascular spaces are too large to be readily obliterated by the doses of radiation usually employed.

In our experience naevus vinosus, or port wine stains, do not obey the usual laws of sensitivity to irradiation. Our results were poor with either radium or roentgen therapy, regardless of the age of the individual. Although port wine stains are capillary hemangiomas, we have no explanation as to why they do not respond to irradiation. They have no definite afferent and effer-

Fig. 5.—A, the usual amount of scar for a good result in a fair-sized hemangioma of the arm. B, large cavernous hemangioma of the back. The photograph was taken on admission. The patient was treated with three radium applications. Infection followed. A year later there was still a large amount of hemangioma and scarring. Excision advised but refused. In this type irradiation reduces the vascularity and thus makes excision safer.

ent vessel, usually are not elevated and do not pulsate. Of the present series 5.3 per cent were port wine stains, all of which were on the face.

Electrosurgery.—Superficial electrodesiccation and interstitial electrocoagulation are the second most common forms of therapy used in our clinic. Twenty-five per cent of all cases in this series had electrosurgery, alone or combined with radiation therapy. It is used for very small hemangiomas, especially if they are elevated and have a narrow base, i. e. less than 0.5 cm. in diameter. Many of these were resistant to treatment by solid carbon dioxide. Electrodesiccation for superficial lesions leaves the largest scar of any type of therapy, especially when used in large growths, and is therefore justifiable only when the lesion is quite small.

Interstitial coagulation is used in cavernous hemangiomas that have not responded well to irradiation (fig. 7 A, B and D). In many of these cavernous hemangiomas there is a larger portion of the tumor in the subcutaneous tissues than on the surface (fig. 7 D). The extent of this subcutaneous involvement is outlined

by the elevation and characteristic bluish discoloration. All the cavernous growths are first treated by one or more external applications of radium. Several months is required to obtain the full benefit of this irradiation, and then the residual hemangioma is treated by interstitial electrocoagulation (fig. 7 A, B and D). Because of location or large size, a few of these lesions are not suitable for electrocoagulation and excision is preferable. Radium makes these tumors less vascular and excision is safer. Our technic of interstitial coagulation is as follows: A very fine electrosurgical needle is inserted into the tumor and a coagulating current is turned on for approximately five seconds, or until the growth begins to look pale. This same procedure is done throughout the tumor, the needle insertions being equidistant and about 0.3 cm. apart. One such treatment is usually sufficient. The secret of success is a mild current which does not cause too much coagulation. This treatment is usually carried out under local anesthesia. Procaine hydrochloride anesthesia has the disadvantage that it causes edema of the tissues, an objection easily met by using a concentrated solution (2.5 per cent) and injecting at a 1 or 2 cm. distance, making a circular block anesthesia. The only complication of interstitial electrocoagulation is slough, which is always caused by overcoagulation and should be avoided. Experience is the best teacher in determining the optimum amount of coagulation necessary for a particular growth.

Solid Carbon Dioxide (carbon dioxide snow, "dry ice").—The third most common form of therapy we have used is solid carbon dioxide. It has won the favor of pediatricians throughout this country, but radiologists and plastic surgeons have been less enthusiastic about it. Solid carbon dioxide causes the disappearance of the growth by the production of obliterative endarteritis and mild sclerosis of the surrounding stroma. If overdone, i. e. when used over ten seconds at one time, it acts as a caustic and may produce ulceration. It acts more quickly than irradiation and can be used more often, but it is not as efficient as a sclerosing agent. We have used it only for capillary hemangioma. Its action is too superficial to be of much value for a cavernous growth. Solid carbon dioxide is applicable for three types of hemangioma: 1. It is used for the small capillary variety, i. e. less than 0.5 cm. in diameter. It is hard to concentrate radium element in a plaque or roentgen rays into an area of such small size without the risk of resultant sclerosis, pigmentation and skin atrophy from irradiation of larger extent than the original growth (fig. 6 C). Solid carbon dioxide has the advantage that it can be cut to the exact size and shape of the lesion before treatment so that the scar, if any, will be no larger than the original growth. 2. Solid carbon dioxide is used for any patchy area of residual growth around the margins of a hemangioma previously treated by irradiation. It is true that further irradiation in these cases might cause a disappearance of the remaining hemangioma, but with this added irradiation there is a possible danger of increasing the amount of scarring, atrophy or telangiectasis. 3. Solid carbon dioxide is used in several areas where irradiation is contraindicated or mechanically impossible. We here record the twentieth case of hemangioma of the scrotum. It was successfully treated by solid carbon dioxide. Obviously, irradiation over the scrotum in infants is not without question and may be open to criticism. Testicular tissue is known to be very radio-

sensitive. Although we feel that the amount of irradiation required to eradicate hemangioma of the scrotum is probably insufficient to damage the deeper lying testicle, until further work has been done to determine the radiosensitivity of an infant's testicle it would seem safer not to use this form of therapy for hemangioma of the scrotum. The redundancy of the skin of the scrotum makes surgical removal relatively simple. Because of the inverse square law, damage to the ovaries would not be expected when treating hemangioma of the vulva. Solid carbon dioxide was much simpler to use in our case of hemangioma of the scrotum than surgical excision or electrodesiccation. It gave a nice result.

Solid carbon dioxide is used for almost all capillary hemangiomas about the eyelids, internal canthi, external canthi and adjoining regions (fig. 7C). It is mechanically almost impossible to keep radium directly on these lesions because of the constant movement of the eyelids. The eye is very resistant to irradiation, especially in the mild doses given for hemangioma, but the possibility of radium damage must always be borne in mind. With adults it is quite possible to protect the eye with lead plates of various shapes and sizes, but this is obviously impossible to do with infants.

Our technic for carbon dioxide therapy consists of direct application for from five to ten seconds, repeated at intervals of two months until the desired effect is obtained. The only important complication is ulceration, which can usually be prevented by using less intense freezing, never lasting over ten seconds at one séance.

Sclerosing Solutions.—Our experience with sclerosing solutions is not sufficient to warrant accurate comment. Malkin⁷ has been successful with this form of therapy for hemangioma of the eyelid. Andrews and Kelly⁸ had satisfactory results in twenty cases. They claimed improvement even for port wine stains. It seems that a more extensive use of this agent is necessary before it can be accurately compared with other methods.

Interstitial Radium.—This has never been used in our clinic for hemangiomas. Where used, however, it has practically the same indications as outlined for interstitial electrocoagulation. Brown and Byars⁹ advocate this type of therapy and have been successful with it. External irradiation is the best of all sclerosing agents, as the rays diffuse equally throughout all parts of the growth. We believe it is possible to give as much irradiation as is safe for a particular hemangioma by the external method without having to resort to radium element needles or radon seeds interstitially.

Surgical Excision.—This is probably the oldest form of eradication of hemangiomas. Many times it is the quickest way of eliminating the disfigurement, especially when the lesion is located in skin that can be easily closed, i. e. on the back, abdomen, chest and occasionally face. About the eyelids and lips, particularly when the mucosa of the mouth is involved, excision may necessitate extensive plastic procedures. Such measures are not without residual scarring. To obtain the best surgical cosmetic results in extensive cases, two or more operations may be required. Surgical treatment of hemangioma means hospitalization and

general anesthesia, the latter not without some risk, slight to be sure. All this was avoided in 87 per cent of the cases by using proper irradiation or irradiation followed by touching up small areas with solid carbon dioxide, with cosmetic results comparable to surgical scars. In this series surgical excision has not been performed. In private practice we have had an occasional case which required surgical excision after irradiation.

Port Wine Stains.—Two cases of naevus vinosus, or port wine stains, were treated by radium alone or combined with roentgen therapy. This work was more or less experimental. There was usually some fading out of the redness, but as a general rule the results were unsatisfactory. The preferable treatment for port wine stains is surgical excision if possible, followed by skin

Fig. 6.—A, atrophy of skin and loss of hair following radium treatment. Hemangioma developed by the side of the original growth. Early treatment usually prevents this extension. B, infected hemangioma on the popliteal space, the result of recent irradiation and trauma from scratching. This will leave an unsatisfactory scar. C, patches of residual hemangioma, telangiectasis and scarring following three radium treatments and several applications of solid carbon dioxide. A typical poor cosmetic result. This will improve with age. D, residual patches of hemangioma of the forearm and mild scarring following radium therapy. A typical poor result from radium. Excision to follow.

grafting when necessary. We have not used ultraviolet irradiation, but in the hands of some men, notably Blaisdell¹ and McCollum,¹⁰ it has given promising results. McCollum advises giving one erythema dose weekly for from four to nine months, using an air-cooled ultraviolet Kromeyer lamp. He reports 80 per cent of his patients well or much improved.

COMPLICATIONS AND RESIDUALS

The complications following radiation therapy are immediate (within two or three weeks) or late. The most important immediate complication is infection

(fig. 6 B). It was seen in a few cases of overirradiation, with blister formation, scabs and other features. It may also follow trauma to the growth. Infants often cause irritation by scratching a freshly irradiated area. Several patients in this series were infected and had ulceration on admission. All patients who have infection, with or without irradiation, are always left with more scar (fig. 3 B).

There are several late residuals and they are present, in order of their frequency and importance, about as follows: (1) sclerosis, (2) telangiectasis, (3) residual tumor, (4) increased pigmentation, (5) atrophy of skin, (6) loss of hair, (7) chronic radium ulcerations and (8) epiphyseal injury.

1. *Sclerosis*.—To a varying degree sclerosis of tissues follows practically all therapeutic doses of irradiation

Fig. 7.—A, residual of the lip following radium therapy. Interstitial electrocoagulation with a good result. B, the usual poor result after interstitial electrocoagulation was advised but refused. C, typical hemangioma of the eyelid. Solid carbon dioxide or electrodesiccation is the proper therapy. D, a large subcutaneous cavernous hemangioma of the back after three radium treatments. Notice some residual growth present. Interstitial electrocoagulation is the proper treatment for this residual of subcutaneous hemangioma.

for hemangioma. Sclerosis is spoken of as a complication only when the scar tissue is thick and tough enough to give a poor cosmetic result. Sclerosis results from overirradiation, an insufficient filter or direct contact radium. One treatment of radium for hemangioma should never be above 250 milligram hours, preferably from 175 to 200 milligram hours, using the technic outlined previously. Beta rays from an insufficient filter, secondary rays from the primary filter, and direct contact radium are frequent causes of sclerosis; hence the importance of proper filtration. The scarring may be even or patchy. When present to such an extent that the cosmetic result is poor, excision is the proper therapy. It is the most common late residual but not particularly noticeable except in a few cases.

2. *Telangiectasis*.—This is a fairly frequent residual. In a general way the number of patients showing it is directly proportional to the quantity of radiation given. Our observations are that the quality of radiation makes no difference. It is often very difficult to distinguish between residual hemangioma and telangiectasis (fig. 6 C and D). This is a very important differentiation because hemangioma needs more treatment, but further irradiation would very likely accentuate telangiectasis. As a general rule telangiectasis occurs around the periphery of a treated growth, the vessels have a spider web distribution, and it disappears poorly on pressure.

3. *Residual Tumor*.—Residual patches of hemangioma (figs. 3 B, 6 C and D) are a fairly frequent and very unfortunate complication. They may follow even after several radium treatments. Our explanation for this has been given in a previous paragraph. Residual tumor occurs more often in cavernous hemangioma than in the capillary form. Residual hemangioma in the capillary type of growth is treated by solid carbon dioxide and occasionally electrodesiccation, while residual patches in the cavernous type are treated by interstitial electrocoagulation. In a few of these cases surgical excision with skin grafting if necessary may give the best plastic result. This is one of the most important of all residuals.

4. *Increased Pigmentation*.—Increased pigmentation occurs to a slight extent in almost every case immediately after irradiation. The amount of pigmentation is generally in direct proportion to the amount of radiation given. This increased pigmentation fades out with time, the improvement being greater the younger the patient.

5. *Atrophy of Skin*.—Atrophy of skin may result from three causes: (1) pressure of the underlying tumor, (2) invasion of the skin by the proliferating blood vessels of the tumor, and (3) overirradiation. In many hemangiomas there is a mild degree of the first type of atrophy, occasionally sufficient to leave an appreciable atrophic scar. Overirradiation and an insufficient filter are the more common causes of skin atrophy. It occurred to a marked degree in only 1 per cent of this series (fig. 6 A). Atrophy, of course, is closely associated with scarring. Almost every case of marked sclerosis will have a slight amount of atrophy.

6. *Loss of Hair*.—Loss of hair occurs immediately after every irradiation for hemangioma of the scalp. The hair usually returns after several months, but there are cases (2 per cent in this series) in which the hair over the treated area never returned (fig. 6 A). The hair follicles were destroyed. From a fairly extensive review of the literature we were impressed by the fact that this residual effect of irradiation has not been stressed. It is important to bear this depilating effect of overirradiation in mind in planning treatment for hemangioma of the scalp. Probably milder treatments repeated over a longer period may prevent this complication. As a rule, such a bald spot is readily covered by the hair and is not noticeable.

7. *Chronic Radium Ulcerations*.—Irradiation ulcerations are uncommon complications. They occur from overirradiation, improper filters and secondary infections, or occasionally in a blond person whose skin is very radiosensitive. This has never occurred in our clinic, but a busy plastic surgeon will see it a few times every year. Davis and Wilgis¹¹ and many others have stressed the importance of irradiation injuries.

11. Davis, J. S., and Wilgis, H. E.: Treatment of Hemangiomata by Excision. *South. M. J.* 27: 283-290 (April) 1934.

8. *Epiphysial Injury.*—Epiphysial injury with later disturbance in the growth of bone is an uncommon complication of irradiation. With proper irradiation by radium, the depth dosage is usually too small to cause epiphysial injury. High voltage roentgen therapy is more penetrating and will cause epiphysial injury, but the usual small doses used in treating hemangiomas should seldom cause permanent damage. We have not seen epiphysial injury in this series. Plastic surgeons, for instance Davis¹¹ of Baltimore, emphasize the possibility of this complication of irradiation.

RESULTS

Every new patient who comes to the Oncology Clinic of the School of Medicine of the University of Maryland is seen by a radiologist and a surgeon for an unbiased opinion on the proper therapy. In discussing results we consider any and all forms of therapy, whether used alone or combined. Radium therapy is becoming more and more popular throughout the world, particularly in tumor clinics, and this has been by far our most common form of treatment.

Our results are classified as (1) good, (2) satisfactory, and (3) poor.

1. By a good result from radiation therapy is meant the entire disappearance of the tumor with no disfiguring patches of hemangioma, scarring, telangiectasis, atrophy, loss of hair, increased pigmentation, epiphysial injury or other residuals. It is to be remembered that some slight scarring remains after any form of therapy, but our definition of a good result is one in which the amount of scarring is no more noticeable than the fine linear scar following surgical excision. Of this series of ninety-four cases, all of which were superficial, the results were considered good in 40 per cent. The best results were obtained in infants below 2 years of age. After the period of infancy, the good results of irradiation decreased in direct proportion to age.

2. The results were satisfactory in 47 per cent of the cases. In this group also we compare the end results with what might have been accomplished by surgical excision. The reason for this comparison is that surgical excision is the older form of treatment for hemangiomas. Included in this satisfactory group are all cases in which there is a slight or moderate amount of scarring or telangiectasis, or small patches of tumor remain, or the tumor is entirely gone but the cosmetic result is only satisfactory. In this group too are placed many of the larger hemangiomas, especially of the face (fig. 3 *A* and *B*), where surgical treatment was out of the question because of the size of the growth or extensive involvement of eyelids, lips or nose. There has been a tremendous improvement in many of these cases, but obviously not a "good" result. In many of these cases the pronounced scarring (fig. 3 *B*) will improve with age, ultimately giving a more satisfactory result.

3. In the group yielding poor results (13 per cent in this series) are included: (1) all port wine stains (5.3 per cent), which are all radioresistant; (2) most hemangiomas in adults which were radioresistant and which were finally treated with electrosurgery or surgical excision, and (3) all cases in which the residuals, such as patches of tumor, telangiectasis, atrophy or loss of hair, were so pronounced that the cosmetic result was considered bad.

There are many who think that primary excision of hemangiomas without previous irradiation is the treatment of choice. They argue that time and expense will be saved by primary excision and that a cosmetic result

equal to or better than irradiation will be obtained.¹² We contend that irradiation gives good or satisfactory results in a high percentage of cases (87 per cent in this series) and therefore that surgical treatment is unnecessary for the majority of hemangiomas. In many cases of failure by irradiation (fig. 6 *C* and *D*) surgical excision gives the same linear scar that primary excision would have given. The cavernous growths that have to be excised surgically are much less vascular and operation is safer if preoperative irradiation has been given.

CONCLUSIONS

It is our opinion that as a general rule radium gives good results in a large percentage of cases of superficial hemangioma. A fairly extensive review of the literature on hemangiomas reveals that most articles deal with case reports of unusual types, successful cures by various methods of therapy advocated by many authors, and general discussions on the pathology of hemangiomas, but there was not much emphasis on the failures, complications and late residual effects of irradiation. The patients with bad results are commonly seen by plastic surgeons and do not return to the irradiation therapist unless carefully followed.

Radium has its greatest value for capillary and cavernous hemangiomas in young infants. Cavernous hemangiomas are treated best by external radium and, after several months, by interstitial electrocoagulation for the residual growth. External radium is by far the best and gives the most equally diffuse sclerosing effect of any of the sclerosing agents. Irradiation has given poor results in port wine stains.

Solid carbon dioxide is used for very small hemangiomas, residual patches of hemangioma, telangiectasis around the periphery of a lesion previously treated by irradiation, hemangiomas around the eyelids, and hemangiomas of the scrotum.

We believe that good results can usually be obtained in superficial hemangiomas, but only when the surgeon understands the indications, contraindications and limitations of all forms of treatment, including radium and roentgen therapy, the principles of good plastic surgery and electrosurgery. It is certain that a working knowledge of only one type of therapy will not give good results in all types of superficial hemangiomas.

214 Medical Arts Building.

12. The total expense of irradiation of hemangiomas is not comparable to the cost of hospitalization plus surgeon's fees. In private practice rarely is more than \$25 charged for one treatment, and frequently the fee is less. A larger amount may be charged in cases of multiple hemangioma. We calculate radium overhead on a basis of 3 cents per milligram hour; an average treatment then would give an overhead of \$7.50. Whatever is collected over this amount is considered as professional fee and varies with the financial status of the patient.

History of Helium.—Helium was discovered in the sun in 1868 by Janssen and Lockyer by means of the spectroscope. Its existence on earth was demonstrated by Ramsay, who obtained it from the mineral cleavite. It was later found to be a constituent of the atmosphere to the extent of one part in 200,000. Recently it has been found to occur in certain natural gases. . . . In 1923 a patent was registered in the United States Patent Office by Charles Cooke for the use of helium with oxygen for divers, based on the fact that helium has a coefficient of solubility approximately half that of nitrogen, and because it is twice as diffusible. Sayers and Yant in 1926 decompressed animals from 10 atmospheres of helium-oxygen mixtures in from one-third to one-fourth the time necessary for nitrogen-oxygen mixtures and found no toxic effects from the use of helium under high pressures for short periods.—Barach, Alvan L.: *The Therapeutic Use of Gases*, chapter XIII in *The Therapeutics of Internal Medicine*, New York, D. Appleton-Century Company, Inc., 1940.

THE DIAGNOSIS OF NEUROPATHIC JOINT DISEASE (CHARCOT JOINT)

AN ANALYSIS OF FORTY CASES

RALPH SOTO-HALL, M.D.

AND

KEENE O. HALDEMAN, M.D.

SAN FRANCISCO

Although seventy years have passed since Charcot¹ described the type of joint disease which bears his name, physicians are still far from a complete understanding of its development. Its diagnosis is relatively simple if one bears in mind certain clinical and radiologic characteristics; yet the presence of a Charcot joint is frequently overlooked, especially in the early stages. The experiments of Eloesser,² who produced neuro-arthropathies in cats by traumatizing their joints after their limbs had been rendered anesthetic through the severance of the posterior nerve roots, confirm the usually accepted theory of pathogenesis that attributes the development of the Charcot joint to the effect of a single injury or repeated injuries on an articulation which

to the development of a neuro-arthropathy. A similar loss of sensibility in the joint may occur in syringomyelia, injuries to the spinal cord and leprosy. The characteristics of a Charcot joint, in the order of their usual appearance, are an enlargement of the joint resulting from an effusion, a relaxation of its ligaments lead-

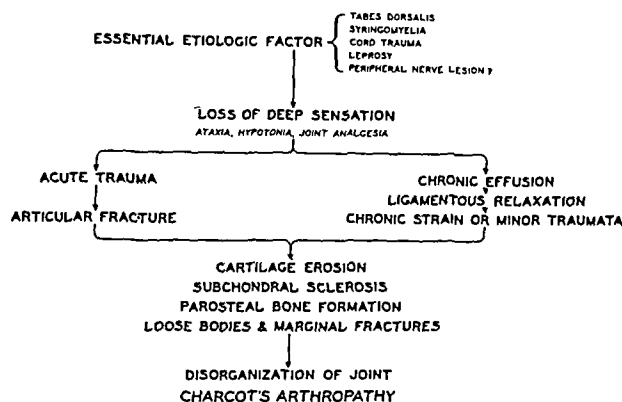

Fig. 1.—Evolution of a neuropathy.

has lost its sensibility to pain. Space does not permit an adequate review of the articles which have dealt with the clinical and pathologic aspects of neuropathic joint disease. Deserving special mention, however, are papers by Key,³ Steindler,⁴ Moritz,⁵ Wile and Butler,⁶ Knutsson⁷ and Potts.⁸

Tabes dorsalis, though most frequently the underlying disease, is not the only condition which may lead

ing to instability and deformity on weight bearing, and thinning of the articular cartilages, marginal fractures, sclerosis of subchondral bone in some areas and atrophy of the bone in other regions, loose bodies in the joint, and the formation of new bone (parosteal bone) outside the joint cavity. Many of these later features are

Fig. 3.—Age incidence: age of onset of Charcot joint.

demonstrated by roentgenograms. The most striking clinical observation is the absence of pain in the presence of such an advanced pathologic process. The foregoing series of changes may be initiated by a fracture in a joint which appears normal. The observations and theories which explain the evolution of a neuro-arthropathy are best shown diagrammatically (fig. 1).

In order to present graphically the clinical picture of a neuropathic joint, a series of forty cases of tabetic arthropathy was analyzed. The series includes the records of both private and clinic patients, about half of whom we ourselves observed. The diagnosis was well established in each case. A comparison of the sex incidence in this series with the observation, by Poole,⁹ of the preponderance of male tabetic patients indicates an equal susceptibility of the two sexes to involvement of the joint, once the underlying disease is present (fig. 2). The average age at onset of symptoms in the joint appears to be between 45 and 50 years (fig. 3), the extremes being 29 and 68 years. The influence of trauma on the development of the arthropathy is seen in the ratio between the number of cases involving the lower extremities, fifty, and the number involving the upper extremities, seven (fig. 4). The importance of severe trauma in the initiation of the series of changes leading to a Charcot joint is further indicated by the history of the onset of symptoms immediately following an acute injury in eighteen cases, or almost half of the total number. The tendency to bilateral involvement is seen in sixteen cases in which two or more joints were affected. In this group both knees were involved in seven cases, both hips in four cases, both ankles in one

Fig. 4.—Joint involvement.

case and both wrists in another case. This occurrence of multiple Charcot joints in 40 per cent of our entire series, as compared with the usually accepted incidence of arthropathy in tabes dorsalis (6 per cent in a group of 744 cases of tabes cited by Moore¹⁰), suggests that certain victims of tabes have a predisposition to involvement of the joints. The importance of the careful observation of the pupillary and deep reflexes is shown by their almost universal impairment in the cases in our series (fig. 7), in contrast to the unreliability of the usual laboratory tests for neurosyphilis in the stage of the disease at which the arthropathy appears (fig. 8).

The microscopic changes which occur in the various components of a joint during the development of a neuro-arthropathy were described by Steindler⁴ and by Moritz.⁵ Studies of microscopic sections from eight Charcot joints in our series indicate that the primary pathologic process is a degeneration and partial disappearance of the articular cartilage which is invaded by fibrous connective tissue from the pannus on its surface (fig. 5). In certain areas the zone of preliminary calcification is exposed by the stripping away of cartilage. Beneath this zone there may be a proliferation of cartilage which becomes converted into

subchondral bone, thus accounting for the sclerotic eburnated bone seen at the base of large defects in the articular cartilage (fig. 6). A generalized atrophy of

Slightly reduced from a photomicrograph with a magnification of 40 diameters.

the trabeculae of the cancellous bone is often seen. In one instance we observed a perivascular infiltration of lymphocytes in the capsule of the knee joint, although such evidence of inflammatory reaction is rare.

Fig. 6.—Articular surface of knee; patient K. S., aged 54, with Charcot knee of three years' duration. C, hyaline cartilage showing partial erosion; B, thickened subchondral bone forming under thinning cartilage; Z, zone of preliminary calcification; M, marrow. Slightly reduced from a photomicrograph with a magnification of 40 diameters.

In addition to the factors which lead to the disintegration of a joint, as shown in figure 1, we observed the presence of pyogenic organisms in an affected

joint, as previously reported by Shands.¹¹ This author, in studying the synovial fluid from ten Charcot joints, found streptococci in two knees and Staphylococcus aureus in one shoulder. In our series of six joints on which operations were performed, culture of material obtained at operation from one knee yielded a mixture of hemolytic streptococcus and Staphylococcus aureus. In this case the operative wound suppurated and the joint failed to fuse. This experience indicates the importance of obtaining a bacteriologic study of the synovial fluid before operating on a Charcot joint.

SUMMARY AND CONCLUSIONS

1. The diagnosis of a neuro-arthropathy rests on the observation of a swollen, relaxed and disorganized joint which is comparatively painless, in a case present-

KERATOSIS BLENNORRHAGICA

A BRIEF REVIEW AND REPORT ON THE EFFECTS OF HYPERPYREXIA IN ITS TREATMENT

FRANK C. COMBES, M.D.
NEW YORK

CARLISLE DIETRICH, M.D.
TACOMA, WASH.

AND
JULIUS COHEN, M.D.
NEW YORK

In 1893 Vidal¹ described a generalized symmetrical eruption involving the nails in a patient with gonorrheal polyarthritides. In 1912 Simpson² described the first case occurring in the United States. Keim³ in 1924 observed and recorded a similar case in which he made minute microscopic studies and reviewed all the pertinent literature, analyzing the disease from an etiologic angle and differentiating it from pustular psoriasis. Since 1924 there have been numerous additions to our knowledge of this syndrome, particularly concerning its response to treatment. Our purpose is to review briefly the more recent literature and to record studies made on two patients who have been under our care at Bellevue Hospital.

ETIOLOGY

The genesis of keratosis blennorrhagica has been discussed by Gënner and Boas,⁴ Scmazzone,⁵ Rostenberg and Silver⁶ and Ormsby in the discussion of a paper by Ebert and Slepian,⁷ the consensus being that the cutaneous reaction is an allergic expression of a sensitized skin, similar to the conception of the tuberculid reaction. Chauffard and Fiessinger⁸ interpret the lesions as a manifestation of gonococcal septicemia in the presence of a severe arthropathy, although the finding of the gonococcus in the lesions has been infrequent. Barrett,⁹ Wadsack,¹⁰ Campbell,¹¹ DuBois,¹² Hansteen,¹³ Scholtz¹⁴ and Gager¹⁵ report the isolation of a gram-negative diplococcus, but most attempts have been unsuccessful.

Results of efforts to induce lesions artificially by auto-inoculation have been inconsistent. Lees and Percival¹⁶

obtained positive results by scarification, using pus obtained from the urethra. They were able also to produce similar lesions using cultures of gonococci. Sullivan, Rolnick and White¹⁷ produced lesions by inoculation of scarified areas with scrapings taken from the exposed base of a lesion. However, Haase¹⁸ maintains that any abrasion of the skin during the height of the eruption will result in the formation of a keratosis.

INCIDENCE

This type of cutaneous lesion occurs in ratios ranging from 1:5,000 (Harrison¹⁹) to 1:7,500 (Brown²⁰) cases of gonorrheal urethritis. It occurs almost exclusively in men during the third and fourth decades. Arning and Meyer-Delius,²¹ who have had opportunity to study a large number of cases, report its frequency as about 0.46 per cent in 4,300 cases of gonorrheal urethritis. Isaac,²² Lees,²³ Wayson,²⁴ Robert,²⁵ Lévy-Franckel,²⁶ Finlay,²⁷ Beatty²⁸ and Goldmann²⁹ have reported cases observed in women, but in some of them doubt was expressed by the author as to the accuracy of the diagnosis of a coexisting gonorrhea.

The disease is rare; Keim³ in 1924 was able to find only fifty-eight cases in the literature. In 1933 Chambers and Koetter³⁰ listed sixteen additional cases including one of their own. Since then we have found nineteen case reports, making a total of ninety-three.

CLINICAL COURSE

The onset of keratosis blennorrhagica is insidious and follows chronic and recurrent attacks of gonorrheal urethritis associated with chronic prostatitis and seminal vesiculitis. Chills and fever of a septic type herald the appearance of each crop of new lesions. In extensive cases there is profound prostration, anorexia and great loss of weight. The distribution of the eruption is symmetrical. There is a predilection for the soles and palms, genitals and groins. Less often the scalp, dorsum of the hands and feet, forearms and legs are involved. Lesions may also be found on the trunk, but this region and the face are not frequently affected. Barrett,⁹ Berman,³¹ Sherman, Blumenthal and Heidenreich,³² Génner and Boas⁴ and Chambers and Koetter³⁰ report lesions seen on the mucosa of the cheeks, tongue and hard palate.

As long ago as 1899 Buschke³³ recognized a variety of cutaneous lesions occurring in patients suffering from

gonorrheal urethritis. He classified these as (1) simple erythema, (2) urticaria, (3) erythema nodosum, (4) hemorrhagic and bullous exanthems and (5) keratoses. Twelve years later³⁴ he modified this conception, recognizing only the keratoses, interpreting the other lesions merely as evolutionary, in which the dermal inflammatory process had been insufficient in duration or intensity to produce the typical crusts and scales.

Lesions of Palms and Soles.—Briefly stated, the pathologic process consists of vesiculation, pustulation and crusting with associated keratosis. The lesion at its inception consists of an erythematous macule. Hodara³⁵ recognized an urticarial wheal as the earliest manifestation in some cases. Nevertheless this type of

Fig. 1 (case 2).—Keratoses on dorsum of feet.

lesion is short lived, developing into a tiny vesicle surrounded by an erythematous halo. The lesion varies in size from pinhead to about a centimeter in diameter. It arises deep in the epidermis, since it contains an exceptionally small amount of cloudy fluid and may be called a dry vesicle, similar to those so frequently seen in dermatophytids and microbids. In a short time the lesion becomes waxy and almost translucent, like a pustule, although on incision it is perfectly dry. In the center a yellow spot appears, giving it an umbilicated appearance; but on palpation it is found to be a horny excrescence. Sometimes there is a peripherally attached scale suggesting the collaret of Bielt seen in early papules of syphilis in the same location. Often there is definite grouping and confluence of individual papules to form circinate and serpiginous patches with

scaling borders and clearing centers. Half the sole may be entirely covered by one of these caked, heaped-up serosanguineous plaques. It requires approximately three weeks for the development of the mature lesion. Removal of the mass of dried blood, serum and scales exposes a very superficial dusky red, slightly moist, eroded surface with little or no bleeding. If the lesion is untreated, new crusts form. Healing leaves no scar, although Keim observed a slight degree of atrophy in the larger lesions resulting from healing below the rupial crust.

Lesions of the Nails.—Changes occurring in the nails do not differ clinically from those seen in favus and arthropathic psoriasis. There is a heaping up of yellow waxy material beneath the distal end of the nail plate. The nail itself becomes dry, brittle and opaque and is lifted from its base. The free border is rough, broken

Fig. 2 (case 2).—Keratoderma of feet (a large keratosis on the left sole has been removed, exposing the base).

and jagged. These subungual keratomas are tender on pressure and may become painful. They may involve the nail independently or be continuous with keratoses of the adjacent integument of the fingers and toes, in which case there is an associated paronychia.

Lesions of the Mouth.—These consist of flat confluent grayish papules irregularly distributed over the hard palate, cheeks and borders of the tongue. They are usually not numerous and vary in size up to 0.5 cm. in diameter. At their inception they are minute red puncta which rapidly enlarge, so that within forty-eight hours they appear as umbilicated papules with an elevated grayish border. Their developmental cycle is much shorter than that of the cutaneous lesions; they disappear in a few days, leaving only dusky red eroded areas which heal without scarring.

Lesions of the Joints.—The arthropathy usually precedes the cutaneous lesions, although in rare instances it may be entirely absent. It differs from the usual gonorrheic monarthritides in the simultaneous involve-

ment of a large number of articulations. The knee, ankle, wrist and acromioclavicular joints are those commonly affected. The pains are excruciating, but there is not as much redness and periarticular edema as one sees in rheumatoid arthritis or in monarthritic gonorrheal arthritis.

The progress of the disease is chronic with remissions and recurrences accompanied by fresh crops of lesions attending exacerbations of febrile and arthritic symptoms or induced by the therapeutic injection of gonococcus vaccine. Earlier writers expressed the opinion that the application of casts to the legs in the treatment of the arthritis was responsible for the cutaneous lesions.

Pathologic changes in many other organs have been noted by various investigators. These include endogenous conjunctivitis, corneal ulceration, iridocyclitis, anterior synechiae and retinitis. There is an associated general adenopathy in most cases. Acute glomerular nephritis has been reported by Spink and Keefer.³⁶ Other manifestations occurring less frequently include aortitis, pericarditis and endocarditis with large verrucous vegetations on the aortic valves. Tenosynovitis, bursitis and hepatitis with hypochromic anemia have been recorded also as occurring during the course of the disease.

DIAGNOSIS

The recognition of keratosis blennorrhagica is not attended by any great difficulty when one considers the three essential requirements: the presence of gonorrhea, polyarthritides, and the characteristic cutaneous lesions. Jones³⁷ believes that the keratomas may constitute the only symptom other than the original gonorrheal urethritis.

Arthropathic psoriasis in former years offered some difficulty in differentiation. This is not unexpected, since the nail changes in the two conditions are similar and the cutaneous lesions of keratosis blennorrhagica and pustular psoriasis clinically and histologically resemble each other. Feldman³⁸ averred that he could see no difference between the clinical appearance of the two conditions. Silver³⁹ is of the opinion that keratosis blennorrhagica and psoriasis arthropathica constitute one syndrome with a variant etiologic factor. However, there are a few minor differences. Keratosis blennorrhagica at its inception is vesicular and shortly becomes pustular. Plasma cells are usually absent in arthropathic psoriasis. In arthropathic psoriasis there is a much greater tendency to ankylosis and deformity in the affected articulations. Furthermore, endogenous conjunctivitis never occurs in psoriasis.

Differentiation from syphilis may offer some difficulty. The superficial nature of the lesion should be sufficient to exclude the rupial syphilid. Some of the pustules look not unlike the early pustular eruptions but on palpation lack the shotty feeling. Acrodermatitis continua of Hallopeau must also be differentiated.

The search for gonococci in the skin has met with little success. Cole and Driver⁴⁰ found gram-negative intracellular diplococci in a smear from the base of a lesion on a patient's leg and from a miliary abscess on his scalp. The recovery of diplococci on blood culture

has been reported by Roark,⁴¹ who questions the possibility of a contaminant. The demonstration of gonococci in blood smears by Hodara³⁵ is unique and has not been duplicated by other investigators. Although Löhe and Rosenfeld⁴² attach great significance to the gonococcus fixation test, which they believe is regularly positive, as a rule it is of indefinite value and may be negative even with extensive involvement of both skin and viscera.

HISTOLOGY

The histology has been completely discussed by Keim³ and modified by Gans,⁴³ Simpson,² Haase¹⁸ and Rostenberg and Silver.⁶ Briefly, the fundamental changes are epidermal vesiculation with intracellular and intercellular edema. There is a subsequent leukocytic reaction, followed by pustulation with the rapid formation of a dry lamellar parakeratotic scale surmounted by a crust. This crust is often a prominent feature. Because of the predominance of the exudative process in some cases, Rostenberg considered the appellation "dermatitis rupioides arthropathica" a more appropriate name. Haase¹⁸ considers parakeratosis the principal epithelial change. In the prickle cell layer there is a moderate degree of acanthosis with elongation of the rete pegs. In the papillary layer there are edema and an accompanying infiltration of lymphocytes, polymorphonuclear leukocytes, a few eosinophils and plasma cells.

PROGNOSIS AND TREATMENT

The ultimate fate of patients afflicted with this syndrome is variable. An abortive type has been mentioned by Sherman, Blumenthal and Heidenreich,⁴⁴ designated as balanitis sicca circinata, in which the genitalia alone are involved. This type makes an early recovery. The severe generalized form may persist for many months or years, frequently resulting in death from septicemia or some intervening infection.

Modern treatment has improved the prognosis and favorably affected the duration of the disease. Local treatment is of little value. Ointments of resorcinol, salicylic acid and sulfur may be of benefit in their effect on the individual lesions. Autogenous vaccines have been found helpful by Scholtz.¹⁴ Stock vaccines have not been of much value. Drainage of obscure foci in the prostate and seminal vesiclectomy, orthopedic care of the inflamed joints and general supportive management of the patient are indicated. Sherman, Blumenthal and Heidenreich³² think that treatment of the primary focus is of most importance and that local treatment of the cutaneous and arthritic condition is of only secondary value. Infusions, transfusions and a high caloric diet with insulin and an adequate vitamin intake are helpful. Nonspecific protein therapy, copper, arsenic and ferruginous tonics should be given as necessary. Sulfanilamide and sulfarsphenamine have been administered but with indeterminate and inconsistent results. Willmott⁴⁵ had good results using a 1 per cent solution of mercurochrome intravenously.

The most effective therapeutic procedure is the induction of artificial fever by various means. It should constitute the nucleus around which all treatment is

planned. Favorable response to this method has been reported by Willmott,⁴⁶ Cornbleet,⁴⁶ Epstein⁴⁷ and Epstein and Chambers.⁴⁸ Intravenous injections of typhoid-paratyphoid vaccine have not been attended by very consistent results. Epstein and Chambers report rapid improvement following the induction of a temperature in excess of 104 F. by the blanket method. All visible signs of the disease disappeared within a week and the arthritis greatly improved. Early cessation of fever therapy may be followed by a relapse if the primary focus of infection has not been eradicated. This method is valuable when patients are so toxic and debilitated that they cannot successfully withstand surgical intervention. In addition to improvement in the visible lesions and joints there is a rapid favorable response, both mental and physical, such as cannot be obtained by other means.

Fig. 3 (case 2).—Showing lesions of scalp.

REPORT OF CASES

CASE 1.—History.—J. R., a white man, aged 22, was admitted to Bellevue Hospital in July 1937. His previous history was essentially irrelevant. He had gonorrheal urethritis of only four weeks' duration, for which he had had irrigations with a solution of potassium permanganate. Approximately two weeks before admission pain and swelling developed in both knees. Simultaneously there appeared crusted lesions on the soles and penis.

Physical Examination.—The patient had acute gonorrheal urethritis, prostatitis and arthritis involving both knee joints. The latter were red, swollen, tender and flexed at an angle of approximately 160 degrees. There was great limitation of motion, both active and passive, occasioned by the intense pain. The temperature was 102 F. and the pulse rate 100.

On the skin there were three groups of lesions, one on the soles, one on the penis and a third on the tongue. Those

on the soles were more or less confined to the anterior part and heel. They consisted of sharply defined, elevated dirty yellow conical keratomas with a dusky red erythematous halo. They varied in size and in one area had coalesced to form a coin sized patch. Some of the younger lesions were shiny and waxy, suggesting vesiculation. However, puncture of several of these lesions yielded no fluid. On the glans penis were three discrete crusted pea sized lesions. Grouped about the corona glandis and foreskin were several superficial irregularly shaped brownish erosions, the site of previous lesions. On the dorsum of the tongue were three pea sized painless well demarcated flat papules surrounded by a narrow zone of erythema. There was generalized adenopathy.

Dark field examination of the tongue and penile lesions was negative for *Spirochaeta pallida*. A urethral smear showed a few polymorphonuclear leukocytes with a sparse number of gram-negative intracellular diplococci. A blood culture showed no growth. A trichophylin intracutaneous test and a fixation test for gonorrhea were negative.

Treatment.—Ten cc. of azosulfamide was administered intramuscularly daily for sixteen doses with no improvement. Two days after the discontinuance of the medication the patient was placed in the inductotherm and the temperature of his body raised to 106 F. for a period of three and one-fourth hours. The following day his condition was greatly improved. The swelling in his knees had visibly receded and motion in the involved joints was very much increased. One week later the same treatment was administered for three hours. By this time the keratomas had entirely disappeared. Another treatment a week later of one and one-half hours' duration was followed by complete recovery.

CASE 2.—History.—C. G., a Negro, was admitted to Bellevue Hospital in January 1939. He had had several attacks of gonorrheal urethritis during the preceding three years. He had always been a heavy drinker. About the end of November some pain developed in the left ankle with associated redness and edema. Within a few days the left knee, right ankle, right knee and left shoulder were similarly affected, in that order.

Examination.—On admission he was moribund. His weight had decreased from 160 to 105 pounds (from 73 to 48 Kg.). There was extreme wasting of the muscles, especially of the thighs and legs. He suffered excruciating pains in both upper and lower extremities, with complete loss of active motion. All large joints of both extremities were red, swollen and tender. There were moderate limitation of motion and slight swelling and tenderness of the left shoulder joint. Both seminal vesicles were tender and distended, and the prostate was enlarged and boggy.

The cutaneous lesions were generalized but more profuse on the lower extremities. There were two distinct varieties, keratotic papules and irregularly shaped, well defined plaques. The former, which have been previously described in detail, were confined to his hands and feet. Some of them were situated beneath the free border of the nails, which were in some instances elevated from the nail bed and distorted. Irregularly distributed over the back of his feet, hands, legs, forearms, genitals, groins and abdomen were well defined keratotic plaques varying from 3 to 10 cm. in diameter. These were roughly conical and composed of laminated crusts, brownish yellow with a hard irregular surface. The frontal region of the scalp was more or less covered by an imbricated scale the layers of which were cemented together by a dried serosanguineous secretion. This extended beyond the margin of the hair onto the forehead. It was firmly adherent to the underlying skin and on removal left a smooth, superficial, dusky red, dry eroded surface.

Smears from the urethra were positive for gonococci. Examination of the blood on admission revealed erythrocytes 3,800,000, hemoglobin 75 per cent, leukocytes 7,600, polymorphonuclears 64 per cent, lymphocytes 32 per cent, mononuclears 4 per cent, antifibrinogen seven minutes, hemolytic streptococcus agglutination negative, hemolytic streptococcus precipitins (C) plus-minus, coagulation time four minutes, bleeding time seven minutes, Wassermann reaction negative, gonococcus fixation test negative, blood culture (ascitic fluid) negative, blood chlo-

rides 429 mg., blood sugar 89 mg., blood nonprotein nitrogen 32 mg., icterus index 4, van den Bergh test negative.

Treatment.—For one week after admission sulfanilamide was administered in a dosage of 1 Gm. four times daily. In consideration of his profound prostration he was given pills of iron carbonate, viosterol, synthetic vitamin B₁, B₂ and nicotinic acid, 0.1 Gm. five times daily. In addition he received liver extract intramuscularly every other day and five blood transfusions. Under these procedures he rallied and showed considerable clinical improvement, although his erythrocyte count fell to 2,900,000 and his hemoglobin level to 50 per cent. The sulfanilamide had been discontinued but because of a recurrence of pain was resumed, with little benefit.

Beginning on March 3 and continuing at forty-eight hour intervals he received eleven treatments with the inductotherm. At each session his temperature was maintained at 104 F. for a period of from three to four hours. All lesions on his skin promptly disappeared and the arthritis rapidly subsided.

The improvement in his general physical and mental condition was even more striking. In five weeks he gained 40 pounds (18 Kg.) and his blood count returned to normal.

CONCLUSIONS

1. Keratosis blennorrhagica is a distinct entity characterized by polyarthritis and cutaneous keratoses in the presence of a gonorrheal infection.

2. Fever therapy by means of the inductotherm offers a method of treatment superior to any which has been previously suggested.

GALLSTONES IN CHILDREN

REPORT OF A CASE DIAGNOSED BY ROENTGEN EXAMINATION AND CONFIRMED AT OPERATION

VICTOR B. SEIDLER, M.D.

AND

ELIZABETH BRAKELEY, M.D.

MONTCLAIR, N. J.

Only a few years ago the occurrence of gallbladder disease in childhood was looked on as a pathologic curiosity. Not until Potter¹ in 1928 collected 224 cases from the literature, which he reviewed when reporting four cases from his own practice, did the medical profession begin to realize that many of the vague "stomach aches" of children were really manifestations of biliary disease. It is highly probable that this series of collected cases represented the merest fraction of the actual number of children afflicted with some disturbance of the biliary tract, for so firmly fixed was the idea that only adults are subject to gallbladder disease that the possibility was seldom or never considered. Many of the reported cases were accidental discoveries, found when operating for something else (usually acute appendicitis). Worse still, many were found at autopsy.

Ten years later, Potter² again took up the subject of gallbladder disease in childhood and, by instances from his own records and further explorations in the literature, was able to raise the total number of reported cases to 432. While admitting that this shows not so much a greater incidence of the condition in early life as more prompt recognition of a relatively common observation in pediatric practice, Potter is "firmly convinced that, at the present time, gallbladder surgery

in children is several years in arrears of the symptoms. This is emphasized by the fact that a large majority of cases of gallbladder disease in the third and fourth decades give histories of symptoms dating back to the first or second decade."

Our attention was first drawn to the subject of gallbladder disease in childhood by a patient admitted to the Mountinside Hospital, through the pediatric clinic. Reviewing the literature, it is astonishing to find how many cases are on record, yet how seldom the diagnosis is made in the regular routine of hospital admission. Besides Potter's two papers, which cover aspects of the subject completely, there are a number of other isolated case reports of cholelithiasis in children in the literature.³

ETIOLOGY

When biliary disease manifests itself in infants, one naturally thinks of congenital obstruction as a probable etiologic factor. This aspect of the subject has been well presented by Ladd, who studied forty-five cases at the Children's Hospital, Boston. The biliary system, like other parts of the digestive and excretory tract, is subject to various congenital anomalies, several of which may cause obstruction to the ducts. There may be atresia of the hepatic ducts or of the common duct, and the extrahepatic ducts may be missing entirely. The gallbladder may be merely represented by a small cyst having no connection with the common duct or, again, there may be no common or hepatic ducts. There may be stenosis of the common duct and complete obstruction may take place because it is easily plugged with inspissated bile. Or partial obstruction may be due to congenital narrowing of the common duct. Very serious malformations are likely to be manifested by

deep jaundice or other clinical evidences before the infant attains many weeks of age. The majority do not survive, although a few have been completely relieved by operation.

Such a relatively unimportant deformity as congenital narrowing of a duct may, however, give no decided evidence of its presence until the child attains some age, yet the damage to the biliary system is steadily progressing and the symptoms which it continually gives are ignored or misinterpreted. Common duct obstruction has been successfully relieved by anastomosis of the gallbladder to the duodenum (cholecystoduodenostomy), but it is evident that only surgical treatment will enable these patients to outlive infancy.

In older children the etiologic factor in gallbladder disease is more likely to be an acute infection—one of the exanthems, influenza or typhoid fever. Typhoid was formerly incriminated in all types of gallbladder disease, but improvements in sanitary precautions have reduced the incidence of this infection almost to the vanishing point in many communities, yet the number of cases of biliary disease shows no decrease. Scarlet

Fig. 1.—Appearance of gallbladder.

fever is still prevalent enough to account for many instances, and infections of the upper respiratory tract, with influenza, contribute many more. In Lowenburg and Mitchell's series, five children had an associated infection of the respiratory tract. Focal infection and metastasis from a chronically diseased appendix are likewise cited by some writers as prominent etiologic factors in the cholecystitis of childhood. Mention should also be made of the possibility of *Lambli*a infection; as far back as 1928 Smithies found this parasite when doing biliary drainage, and its pathogenicity, when lodged in the biliary tract, has since been recognized by numbers of surgeons operating on the gallbladder and ducts. Twelve of the young patients of Zelditch and his co-workers harbored the parasite, which was recovered in the returns from biliary drainage.

SYMPTOMS AND DIAGNOSIS

In making the diagnosis of gallbladder disease, the physician's task is somewhat complicated if the patient is a child. This is because even at the present time comparatively little is said or written about the prevalence of biliary tract disease in children. Even when a child's complaints are promptly heeded and not placated with some home remedy for a "stomach ache," the possibility of gallbladder disease will not be considered. It is noticeable that many of the cases of

childhood cholecystitis were discovered only when the abdomen had been opened to extirpate a supposedly inflamed appendix. Unlike our patient, the majority of these little patients are brought not to pediatricians but to general surgeons, on whom the task of recognizing the true nature of the abdominal condition usually devolves.

Fig. 2.—Appearance at operation.

The chief diagnostic method is roentgenography. Only three cases have been reported in which the diagnosis was first made by x-rays and later confirmed by operation: one by Beals, one by Montgomery and one by McClendon. Cholecystography is usually well tolerated by children and should be regularly employed with all obscure abdominal conditions, particularly if the child shows even slight jaundice. The routine use of this diagnostic aid would undoubtedly uncover many more cases of gallbladder disease in the early years of life and in this way contribute to better health among the adult population.

The symptoms displayed by children suffering from cholecystitis or cholelithiasis are so similar to those due to appendicitis that confusion between the two is very common. Moreover, it is not unusual for the two conditions to exist simultaneously. Therefore, when operating for appendicitis in a young patient, investigation of the condition of the biliary canal should not be omitted even when the appendiceal features are quite sufficient for all the symptoms.

Several authors have recently stressed the importance of examination of the bile and duodenal intubation in the establishment of a diagnosis of gallbladder disturbance, either suspected or positively recognized. Flakes of mucus, often loaded with leukocytes, were seen by Zelditch and his assistants, and when there was a tendency toward cholelithiasis, cholesterol was demonstrated in the bile.

TREATMENT

In all cases surgical therapy is the only means of relief. Some of the earlier writers on gallbladder ailments in childhood tended to stress the medical side of the picture. But most of those who have recently made contributions to the literature on this subject condemn any undue delay in undertaking surgical exploration.

REPORT OF CASE

History.—A 10 year old Negro girl was first seen in the pediatric clinic with the chief complaint of loss of appetite and weakness, accompanied by jaundice, light colored stools and dark urine of two weeks' duration.

The history, given by the child's mother, was of recurrent attacks of jaundice since the age of 4, sometimes with intervals of no longer than four months. Associated with the jaundice was pain, felt across the middle of the back and on both sides. But there never had been abdominal pain typical of gallstone colic. There had been rheumatic fever at 4 years and, following this, feverish intervals when the child complained of pain in her knees. There had been frequent attacks of otitis media. At about 8 years of age she had been sent to Glen Gardner Tuberculosis Sanatorium with a diagnosis of pulmonary tuberculosis, where she remained thirteen months and was then discharged as having the disease in arrested condition. She was said to have suffered several attacks of jaundice while in the sanatorium, but apparently no investigation of its cause was ever attempted.

Physical Examination.—The patient was well developed and well nourished but looked chronically ill. The conjunctivas were markedly jaundiced. There was a perforation of the right ear drum. The tonsils had been incompletely removed so that some small tags were still in evidence in a throat which was slightly injected. The lungs were clear to percussion and auscultation. The heart was slightly enlarged to the left and there was a loud systolic murmur best heard at the apex and transmitted to the axilla. The liver and spleen were not palpable, and the only positive abdominal indication was slight tenderness on deep pressure in the right upper quadrant.

The patient was admitted to the pediatric ward for complete investigation. The table gives the results of laboratory examinations.

Roentgen Examination.—The plain x-ray film showed a large number of small calcareous stones, mostly in the gallbladder, although four or five were in the cystic and hepatic ducts. Results of study by the Graham dye method were identical.

Laboratory Data

Test	Result
Icteric index	25
Van den Bergh (both direct and indirect)	Negative
Blood phosphorus	4.7 mg.
Blood phosphatase	14 units
Blood cholesterol	176 units
Stool examination:	
Urobilin	present
Bilirubin	absent
Blood count:	
Hemoglobin	55%
Red blood cells	3,130,000
White blood cells	12,900
Polymorphonuclears	56%
Small lymphocytes	44%

Operation.—Because of the low blood count, it was deemed unwise to operate immediately. Two blood transfusions were given and at the end of two weeks the blood had improved

Fig. 3.—The operative specimen.

sufficiently to permit surgical intervention. On April 8, 1939, under gas-oxygen-ether anesthesia, the abdomen was opened by an incision extending from the costal margin to the level of the umbilicus, 1 cm. to the right of the midline. The gallbladder, when exposed, was found to be greatly enlarged and filled with small stones. One stone was found in the ampulla and another at the junction of the cystic and common ducts. The gallbladder was freed and dissected from the liver, the cystic artery identified, clamped, tied and cut; the common duct

was dilated with Lahey dilators as far as the duodenum and the gallbladder was then removed. The wound was closed in the usual manner.

A feature of much interest was a group of glands about the common duct which were enlarged and very firm. One of these glands lay in such a position that it pressed on the common duct, almost completely occluding its lumen. The stone already mentioned lay directly behind the point of compression. The gland was removed and sent to the laboratory for examination.

Pathologic Report.—The gallbladder was thickened and infiltrated with fibrous connective tissue. There were dilated capillaries and focal collections of chronic inflammatory cells. The gland which had been removed showed no tuberculous infection.

Postoperative Course.—At her discharge from the hospital, after an uneventful convalescence, the child's icteric index was 11.

COMMENT

The striking feature of this case is the finding of nontuberculous glands in close relation to the diseased gallbladder. The history of arrested pulmonary tuberculosis would at once suggest their origin, but the laboratory examination did not bear this out. The fact that a stone had formed directly behind the point of compression of the common duct strongly indicates the important role of stasis of bile in the formation of stones.

Examination of the case reports of gallbladder disease in children brought to light two which bear some resemblance to that just related. Patient 4 of Zelditch and his co-workers was sent to the hospital with a diagnosis of tuberculous peritonitis. There had been abdominal pain for more than a month, but no details of a tuberculous history are given. The child was treated with biliary drainage only. Vergelin and Rosenfeld's patient was a girl of 6 years who had active pulmonary tuberculosis at the time the gallbladder symptoms were first manifest. At operation a number of the mesenteric glands were noted as enlarged and palpable as hard nodules along the course of the ducts. No mention is made of these enlarged glands exerting pressure on any of the ducts, but this would seem to be a logical result of caseation of the mesenteric glands, if one accepts the theory of the bile stasis origin of gallstones.

CONCLUSIONS

As nearly 450 cases of gallbladder disease in children under 15 years of age are now on record, disorders of the biliary tract in children can no longer be regarded as rare.

2. Typhoid, once regarded as a common cause of cholecystitis, has now become an unimportant source of morbidity, thanks to prophylaxis and improved sanitation. But the incidence of cholecystitis and cholelithiasis in children has in no wise diminished, so one must look elsewhere for the chief etiologic factors.

3. From the observations at operation in the case here reported, it is probable that bile stasis, induced by compression of the common duct by an enlarged and indurated node, was the basic cause of the cholelithiasis.

4. The diagnosis of biliary tract disease during the early years of life may be reached by the same methods now employed for adults and is in no way more complicated or difficult than with adults. Because the symptoms so closely simulate those of appendicitis, differential diagnosis is often missed. Therefore the pediatrician and the surgeon should be on the alert to recognize gallbladder disease unerringly and to operate promptly when surgical treatment is indicated.

EXPERIENCES IN HEPARIN ADMINISTRATION

ROY D. McCLURE, M.D.

AND

CONRAD R. LAM, M.D.

DETROIT

The control of the coagulability of the blood *in vivo* by the use of heparin in its present highly purified form constitutes one of the significant achievements of medical science during the past decade. The product available today is 500 times more potent than the original crude heparin described by Howell and Holt¹ in 1918 and is 100 times more potent than the material used clinically by Mason² in the Henry Ford Hospital in 1924. In that year Mason reported the experience with heparin as the anticoagulant in blood transfusions in thirty-three human subjects. He used 100 mg. of heparin in 500 cc. of blood. Reactions were frequent, the incidence for three lots being 33 per cent, 100 per cent and 28 per cent respectively. About one-half hour after the transfusions, symptoms developed which varied in intensity from mild headache and chilly sensations to intense headache, backache, vomiting, chills and temperatures as high as 104.4 F.

In animal experiments, Mason³ noted that heparin was efficacious in preventing experimental thrombosis and suggested that it should be applicable clinically. No attempt was made at the general heparinization of a human subject because of the untoward reactions resulting from the injection of enough heparin to render only half a liter of blood incoagulable.

In 1929 Howell⁴ reported that he had purified the material so much that 1 mg. would prevent the clotting of 100 cc. of blood. It had been used in ten transfusions with two chills resulting. The problem of further purification was undertaken by workers in Toronto in 1929. At the suggestion of Dr. C. H. Best, Charles and Scott,⁵ of the Connaught Laboratories of the University of Toronto, did successful research on heparin and produced the present highly purified nontoxic material which we are using. A number of investigators have done valuable independent research on the subject. For a summary of the contributions of Schmitz and Fischer, Jorpes and Bergstrom, Astrup and Jensen and other workers, the reader is referred to the recent comprehensive review by Mason.⁶

After animal experimentation, Murray, Best and their co-workers used heparin on human subjects. Their experiences have been presented in a number of papers.⁷ In Murray's latest paper he⁸ summarizes his extensive

clinical experience with heparin. A group of 440 patients with various operative procedures had been given prophylactic heparinization, and no pulmonary embolism had occurred. Twenty-nine patients with pulmonary embolism had been treated; all of these survived, and with one possible exception there was no further embolism. Eighty-one patients with phlebitis were treated, and it was felt that the clinical course of the treated group was better than that of a control group; no emboli occurred. Six patients with mesenteric thrombosis were given heparin after operation to prevent extension of the process; four recovered and two died of preexisting peritonitis. Heparin was used in eight cases of splenectomy to prevent thrombosis of the portal vein. Embolectomy for peripheral embolism was done twelve times, the artery remaining patent in each instance; two end to end arterial sutures were done (brachial and common carotid arteries) and in one case a venous graft was used to bridge the gap in a popliteal artery left after the removal of an aneurysm. A secondary operation was necessary in the latter case but the result was excellent.

In a preliminary report Kelson and White⁹ showed encouraging results in the treatment of seven patients

popliteal artery, thrombosis of the posterior tibial artery, and phlebitis. The clinical data in the eleven cases are summarized in the accompanying table.

The material consists of 10,000 units of heparin dissolved in 10 cc. of saline solution. (This unit is five times larger than the original Howell unit, which inhibits the clotting of 1 cc. of cat's blood.) We proceeded to give this material to our first patient (W. P., chart 1) according to the simple directions given by Murray and Best in January 1938.⁷

The heparin solution is added to an intravenous saline drip. Usually 1,000 units of heparin, i. e. 10 mg., is added to each 100 cc. of saline solution. The saline and heparin mixture is allowed to run into the vein at such a rate that the clotting time of the patient's blood is maintained at about fifteen minutes, i. e. two or three times the normal value. . . . The rate of saline solution may be twenty-five drops per minute, but this varies greatly from case to case. . . . The clotting time may be determined by one of the simple methods, such as the breaking off of bits of a capillary tube which has been filled with blood.

Chart 1 shows graphically what we were able to do with the clotting time in the first case. Injection of the solution was begun at the rate of 2,000 units an

Summary of Eleven Cases Treated with Heparin by Continuous Intravenous Drip

No.	Patient	Age	Sex	Weight	Operation or Diagnosis	Indication for Heparin	Evidence of Pulmonary Embolism					Approximate Units per Hour Necessary	Total Number 10 Cc. Vials	Chills

who had bacterial endocarditis with a combination of sulfapyridine and heparin.

In the face of the impressive report of Murray, we present our results with heparin administration in a small series of eleven cases. We believe that these patients presented definite if not urgent indications for heparinization; the material was not used from the standpoint of research but was used for the treatment of the individual patients and was paid for by the patients as such. Even in this small series we have had a reasonable opportunity to study the potency of the material in vivo and its possible toxic effects. Several details of the technic of administration have been learned by experience, and a few complications have arisen which are worth recording.

Since April 1939, every patient with postoperative embolism which was not immediately fatal has received general heparinization as prophylaxis against further embolism. We have had eight such patients. Seven of these did not have recurrence of embolism; one had a second infarction five days after the first course of heparin was finished, and a second course was given, with recovery resulting. Three other types of condition have been treated: embolectomy for embolus in the

hour. Two hours after the treatment was begun the patient had a violent chill. In spite of this reaction the treatment was continued. The temperature rose to 103 F. and on two subsequent days there were less severe chills. The rate of injection was varied in an attempt to stabilize the clotting time at the optimum level, and it will be seen that approximately 2,000 units an hour was necessary to elevate the clotting time to fifteen minutes or above. In contrast to this the results in our eighth case are shown in chart 2. The clotting time in this case was easily maintained above the optimum level by the administration of 1,000 units an hour. No chill or other subjective symptoms occurred in this case, indicating that the toxic fractions in the material used in our earlier cases had been removed.

Our third case (N. V., chart 3) is reported in detail because it illustrates a complication that may be expected if one attempts to maintain an optimum clotting time in all patients by giving 1,000 units in 100 cc. of saline solution. Since some patients require 2,000 units an hour, this would result in the administration of 4,800 cc. of saline solution daily. In the presence of healthy kidneys and heart this will be tolerated for a period, but after this edema appears.

A white man aged 24 was admitted July 13, 1939, suffering from fractures of eight ribs on the left side and both scapulas. July 30 he had a sharp pain in the right side of the chest

9. Kelson, S. R., and White, P. E.: A New Method of Treatment of Subacute Bacterial Endocarditis Using Sulfapyridine and Heparin in Combination: A Preliminary Report. J. A. M. A. 113:1700-1702 (Nov.) 1939.

posteriorly and coughed up blood; roentgenologic examination showed probable infarction. Heparinization was begun August 1; he immediately had a chill with rise of temperature to 104 F. August 2 he was comfortable; August 3 a slight expiratory wheeze was noted, and August 4 there was slight increase in respiratory difficulty. The next day generalized edema appeared and the patient was mentally confused. It was evident that these symptoms were due wholly to excessive parenteral intake of physiologic solution of sodium chloride. Therefore the concentration of heparin was doubled. August 6, studies of the blood chemistry showed the chlorides to be 430 mg. (whole blood as sodium chloride), sodium 338 mg., carbon dioxide combining power 77.6 volumes per cent, plasma albumin 2.68 Gm. and globulin 1.65 Gm. The alkalosis and the marked dilution of the blood as indicated by the low plasma proteins values were notable. The edema did not disappear rapidly, and August 7 a 5 per cent solution of dextrose was substituted for the saline solution. This resulted in marked diuresis and rapid disappearance of the edema. A mild saphenous phlebitis resulted from the use of dextrose as the infusion medium, but the patient had no further embolic manifestations and was discharged on September 2.

When a person with cardiac insufficiency is treated with heparin, the matter of the injection of saline solution into the blood stream is of the greatest importance. This may explain why it was necessary for Kelson and White to discontinue prematurely the treatment in four of their seven cases of endocarditis. Our seventh case

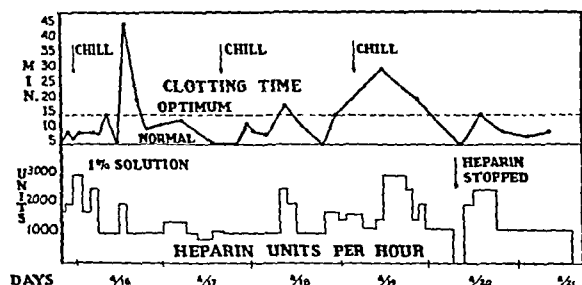

Chart 1 (W. P.; herniotomy; embolism ninth day).—Heparin chart of the first patient in the series, showing that 2,000 units an hour was necessary to maintain the clotting time at fifteen minutes or above (capillary tube method).

(G. L. in the table) illustrates a satisfactory result from peripheral embolectomy in spite of the fact that it was necessary to stop the heparin early because the patient would not tolerate the amount of saline solution necessary to give the heparin in a concentration of 4,000 units per hundred cubic centimeters.

A white man aged 62 had been treated for arteriosclerotic heart disease with auricular fibrillation since 1937. He had had seven admissions for congestive failure. Oct. 10, 1939, he was admitted on the service of Dr. F. J. Smith for treatment of myocardial failure. November 4 there was sudden loss of vision of the left eye, and ophthalmologic examination revealed central retinal thrombosis. At 8 a. m. November 6 he had sudden severe pain in the left popliteal space. Examination of the leg showed it to be blanched and cold below the knee. There was no pulse in the posterior tibial artery, but a faint pulse could be felt in the upper part of the popliteal artery. The pain was excruciating and was not controlled with morphine. The diagnosis of embolus to the bifurcation of the popliteal artery was made. General heparinization was begun at once, so that when the patient was brought to the operating room the clotting time was twice normal. Operation (R. D. McC.) was begun at 11 a. m. under general anesthesia. The popliteal artery was exposed and the embolus palpated and removed after incision of the artery. The sclerotic artery was sutured with arterial silk, and when the proximal serrefine clamp was removed there

was immediate pulsation in the posterior tibial and dorsalis pedis arteries. Heparinization was maintained throughout the operation.

When the patient reacted from the anesthetic, his gratitude for the relief of the agonizing pain of ischemia was notable. It was planned to give heparin for a week, but on November 11, the fifth day, Cheyne-Stokes respirations and signs of increas-

Chart 2 (A. R.; herniotomy; embolism fifth day).—Heparin chart of eighth patient in the series, whose clotting time was easily maintained at the optimum level by giving 1,000 units an hour. Note the absence of chills.

ing myocardial failure developed, and it was deemed imperative to discontinue all intravenous fluids. There was slight oozing of the wound, which was easily controlled with pressure dressings. The circulation of the foot remained excellent. The patient had marked diuresis from a mercurial diuretic, a hydrothorax was tapped November 20, and he was discharged December 12.

Our eleventh case (W. K.) is reported in detail because of the complications encountered and the marked change in the method of administration of the second course of heparin:

A white man aged 69 had a suprapubic cystotomy Feb. 15, 1940, and on February 26 the second stage of the prostatectomy was done. Three days later there developed pain and a friction rub in the left chest. Injection of heparin in 2 per cent solution was begun. On March 3 auricular fibrillation was noted, and it was felt that some degree of cardiac decompensation existed. He was digitalized, and the heparin was continued in 4 per cent solution. On March 8 he was drowsy and there was slight pitting edema of the sacrum and left ankle. It was felt advisable to discontinue the heparin and allow the patient to get up. Activity had progressed to the point where he was walking in the hall on March 13. That night sudden pain developed in the right axilla. It was evident that a second infarction had occurred, but the cardiorespiratory consultant advised against the administration of any considerable quantity of fluids intravenously on account of the previous experience. On March 14 there was a loud leathery friction rub over the right axilla. On March 15 it was decided to try the intermittent injection of the undiluted heparin solution. A previous report¹⁰ had shown that three injections over a period of six hours gave a maximum elevation of clotting time of fifty-four minutes.

Chart 3 (N. V.; fracture of scapulas and nine ribs on left; embolism seventeenth day).—Heparin chart. The patient had edema on the fifth day from excessive saline intake. The black area indicates the reduction of fluid obtained by doubling the concentration of heparin.

Chart 5 shows the effect on the clotting time of 104 injections over a period of twelve days. Injections were made every two hours for three days, and every three hours thereafter. Clotting times were determined just before an injection and ten

10. Luccia, S. P., and Aggeler, P. M.: Heparin and the Blood Coagulation Mechanism, *Proc. Soc. Exper. Biol. & Med.* 40: 41-45 (Jan.) 1939.

minutes after, to ascertain the minimum and approximate maximum range. This schedule was possible only because the patient was exceedingly cooperative and did not object to the numerous injections. It will be noted that the clotting time was kept fairly well above fifteen minutes for twelve days by the use of slightly over forty-one 10 cc. vials by the intermittent method, while thirty-eight vials were used in eight

Chart 4 (S. K.; perforated appendix; embolism twelfth day).—Heparin chart.

days when the material was given by continuous drip. On March 22 he was given a light general massage, which was repeated on subsequent days. He was allowed up on March 27, but the heparin was not stopped until March 27, when he was staying up most of the day and walking in the hall. There was no further evidence of embolism and at no time was there abnormal bleeding from the prostatic bed.

We have treated only one case of phlebitis with heparin:

A man of 42 had signs of peritonitis, but he improved on conservative treatment. After one month in the hospital phlebitis of the right leg developed, with severe pain. He was heparinized for six days. During this period there was no progression of the phlebitis and he was more comfortable, although there was no effect on the fever. Several days after the heparin was discontinued, phlebitis appeared in the left leg.

Another case (J. M. in the table) will be reported in detail, because it is the first of its type to be reported. It represents a favorable result from a combination of treatment with passive vascular exercise and heparin in a case of occlusion of the posterior tibial artery:

A white man aged 35 had a positive Wassermann reaction July 22, 1939, and a paretic gold curve December 16. Feb. 10, 1940, he had five hours of fever therapy in the hyperthermia, the treatment being over at 2:30 p. m. At 4 p. m. he complained of cramping in both legs. This was relieved somewhat by the injection of calcium gluconate and he went home. The pain in the left leg persisted and he was readmitted to the hospital during the night. Several hours later he was seen by a surgical consultant, who confirmed the evidence of arterial occlusion. The first, second and third toes of the left foot were cold and mottled. Coldness and insensitivity to pinprick extended for 2 inches up on the foot on both dorsal and plantar aspects. There was no pulsation in the posterior tibial artery as compared with a good pulsation on the right. The dorsalis pedis pulse was questionable on both sides. It was felt that the occlusion was probably the result of thrombosis on account of the presence of syphilis, the absence of a detectable heart lesion and the history of recent hyperthermia treatment. Passive vascular exercise and heparinization were suggested and carried out. After the extremity had been in the boot for ten minutes there was noticeable improvement in the color of two of the smaller toes, although no posterior tibial pulse was palpable. Heparin was begun and the clotting time was elevated to fifteen minutes. The next morning, after eighteen hours of the combination treatment, the posterior tibial pulse was present, although it was weaker than that of the other side. All of the foot was pink except for a small area about 2 mm. wide at the lateral border of the great toe. Passive vascular exercise was discontinued after one day and heparin was continued for another day. There was no further evidence of circulatory deficiency in the foot. The physical therapy was probably the most important factor in the good result, with heparinization a valuable adjunct.

POTENCY AND TOXICITY

The potency of heparin obtained from different laboratories may vary markedly. This fact, together with the fact that there is no official standard of potency, causes confusion when results are compared. The unit referred to in this paper is that of the Toronto workers, namely the activity of 0.01 mg. of the crystalline material. Dr. Best¹¹ believes that the potency of this product is perfectly constant. There is, however, considerable variation in the amounts required for different patients.

In general, the potency in vivo has not been as great as we had expected after reading the previous reports. As indicated in the table, seven patients required approximately 2,000 units an hour to keep the clotting time above fifteen minutes, one required 1,500 units, and three required 1,000 units. The two females in the series were in the last group. The weight of the patients was not significant. Chills and fever, the only toxic effect observed, occurred in the earlier cases, but no such effect was noted in the last five consecutive cases. The price of heparin has come down appreciably since we began using it. The daily cost may not exceed \$10 or \$15, which is no more than the cost of special nurses.

DETAILS OF TREATMENT

It is convenient to give the heparin in 2 per cent¹² solution although, if there is indication to restrict fluids, more concentrated solutions may be used. In one case there was no ill effect from repeated injections of the undiluted solution. When the continuous intravenous drip is used, the vein selected may be in the leg or arm. It is more convenient for the patient for the needle to be in the leg, thus leaving both arms free for eating, reading and personal care. In most instances we have inserted a medium size intravenous needle into the vein

Chart 5 (W. K.).—Effect on the clotting time of repeated intravenous injections of 4 cc. of undiluted heparin solution at intervals of two and three hours over a period of twelve days.

and taped it firmly in place, without the necessity of "cutting down." The leg is not splinted; on the contrary, after a day or two the patient is encouraged to move all extremities at will. In an uncooperative

11. Best, C. H.: Personal communication to the authors.
12. The term "2 per cent" refers to the dilution of the "Solution of Heparin" supplied by the Connaught Laboratories. Since this solution consists of 100 mg. of crystals in 10 cc. of saline (1 per cent) solution, the concentration of crystalline heparin in our "2 per cent solution" is actually only 0.02 per cent.

patient, such as the man with tabetic dementia paralytica in our series, it is essential to fasten a cannula in the vein by ligature. When the patient is sufficiently recovered from his operation or infarction to be ambulatory, the needle may be transferred to a vein in the forearm, after which he may sit in a chair or walk about the room with the intravenous injection running. How long the patient should be ambulatory before the heparin is discontinued is not known; we have felt that two days should be a reasonable period.

SUMMARY

1. Eight patients with postoperative pulmonary embolism have been treated by general heparinization. All recovered, but one required a second course of heparin when a second infarction occurred five days after the first course was ended.

2. Heparin was used with gratifying results in one case of embolectomy of the popliteal artery and one case of probable thrombosis of the posterior tibial artery.

3. The purified heparin that is available at the present time is nontoxic when given intravenously. It is economically feasible to use heparin in the treatment of selected cases.

4. Considerable variation in the amount of heparin necessary to elevate the clotting time to an arbitrary optimum level in different patients has been observed.

THE INTERPRETATION OF VISIBLE PULSATION IN THE RETINAL ARTERIES

JOHN E. L. KEYES, M.D.

CLEVELAND

AND

WILLIAM F. HATCHER, M.D.

YOUNGSTOWN, OHIO

Our purpose in this communication is to discuss an error that persists in ophthalmic literature concerning the interpretation of pulsation of the retinal arteries.

Two years after Helmholtz¹ announced his discovery of the ophthalmoscope in 1851, Van Trigt² and Coccius³ observed a venous pulsation on the papilla. The following year (1854) Jaeger⁴ described an arterial pulse in the retinal arteries and von Graefe⁵ noted retinal arterial pulsation in glaucoma. Since then, many observations have been published on pulsation of the retinal blood vessels. The opinion that pulsation of the retinal veins is physiologic, but that pulsation of the retinal arteries is always pathologic, became established in ophthalmic literature and persists to date. When it became possible to observe the fundus of the eye more minutely as the result of improvements in the ophthalmoscope, a few observers expressed doubt that a pulse in the retinal arteries is always pathologic. One of the conclusions of Ballantyne⁶ in his comprehensive article, published in 1913, on "Pulsation of the Retinal Arteries" was that pulsation of the retinal arteries is

sometimes physiologic. He found an arterial pulse of some kind in 36 per cent of 100 presumably healthy outdoor patients at an eye infirmary and concluded "it is likely that 36 per cent is an under, rather than an over, estimate of the frequency of the pulse."

A survey of eight textbooks on ophthalmology in English, published or revised since 1933, reveals that in five of these books the erroneous statement persists that pulsation of the retinal arteries is always pathologic. No mention was made of the subject of pulsation of the retinal arteries in one book. One author avoided the issue. In only one of the eight textbooks is it clearly stated that pulsation of the retinal arteries is a normal occurrence.

Recent evidence of the persistence of this fallacy is afforded by the 1939 edition of a small textbook of the diseases of the eye which enjoys probably the widest distribution of any ophthalmic textbook in America. Writing of pulsation in the retinal blood vessels, the author of this book states that "pulsation in the veins is often seen in health, but arterial pulsation is always pathological."

The arteries of the retina are not exempt from manifestations of the arterial pulse. The retinal arteries normally function under a mean intra-ocular pressure of 20 mm. of mercury (Schiötz). This intra-ocular pressure does not prevent an arterial pulse but renders it more readily visible. This fact was noted by von Graefe in 1854, when he recorded an accentuation of the arterial pulse, when the intra-ocular tension is increased digitally, or in glaucoma.

Skilful and careful observation will reveal a pulse in at least one branch of the retinal artery in as many as 80 per cent of cases that are suitable for ophthalmoscopic study. Such minute details as movements of the arteries will not be seen in restless, uncooperative patients or in eyes with hazy refractive media or a high degree of simple or compound refractive error.

It is not difficult to observe movement of the retinal arteries with the aid of an electric ophthalmoscope or even with a reflecting ophthalmoscope, employing the direct method of ophthalmoscopy. In many instances a retinal arterial pulse can be seen in the blood vessels near the optic disk through an undilated pupil. The arteries can be examined more minutely and over a larger area of the fundus if the pupil is dilated. As an aid to the beginner in ophthalmoscopy, digital pressure on the anesthetized eye, or through an eyelid, is helpful in that it accentuates the amplitude of the arterial pulse. A pulse wave of good amplitude can usually be seen in the eyes of a person suffering from aortic valvular disease.

To avoid error due to inexperience and difficulties, such as confusing retinal light reflexes, we recommend acceptance of only those ophthalmoscopic details seen by two or more observers, which has been our practice for several years.

Pulsation of a retinal artery has been observed on the disk, in the retina near the papilla and in its visible peripheral branches. The most favorable place to see pulsation is at a bend in the course of a tortuous artery. At such a location a decided lateral movement of the artery synchronous, or nearly so, with the radial pulse is usually visible. Close observation of the movement of a retinal artery in the region of a bend or curve reveals that the movement of the vessel is toward the convexity of the curve. At an S curve this movement is particularly noticeable because it travels in opposite directions. A pulsating forward and lateral movement

5. von Graefe, Albrecht: Vorläufige Notiz über das Wesen des Glaukoms, Arch. f. Ophth. (pt. 1) 1: 371, 1854.

6. Ballantyne, A. J.: Pulsation of the Retinal Arteries, Ophthalmoscope 11: 271, 338 and 460, 1913.

of an artery synchronous with the pulse is frequently observable at a bifurcation. The most common evidence of an arterial pulse wave is a rapid lateral movement and slower recoil of a vessel. There is, however, also an expansile movement of the arteries which manifests itself by an alternate widening and narrowing of the arterial light reflex. This expansile pulse is usually the only type of pulsation visible in a straight artery. In healthy persons the locomotor type of pulsation is more easily seen than the expansile type. The rarest type of pulsation is the capillary pulse. It is manifested by an alternate flushing and paling of the papilla and may be seen in persons with aortic insufficiency.

In considering the various types of pulsation seen in the retinal arteries, it should be remembered that they are manifestations of an expansile and elongating effect, produced in the relatively unsupported retinal arteries by the passage of the systolic pulse wave. While the cause of the pulsation is constant, the effect varies in straight or tortuous portions of the arteries.

It is not within the scope of this paper to discuss the pathologic conditions in which the normal pulse of the retinal arteries may be altered. Suffice it to state that certain general and local diseases alter the character of the retinal arterial pulse.

SUMMARY

A visible pulse in the retinal arteries is a common physiologic phenomenon. This varies with general and local disturbances of circulation and of the eye. Statements to the effect that pulsation of the retinal arteries is always pathologic should be corrected in textbooks of ophthalmology.

THE TREATMENT OF DELAYED MENSTRUATION WITH PROSTIGMINE

A THERAPEUTIC TEST FOR EARLY PREGNANCY

SAMUEL SOSKIN, M.D.

HANS WACHTEL, M.D.

AND

OSCAR HECHTER, B.S.

CHICAGO

In a recent study¹ it was found that the various component phenomena of estrus in the rat may be classified in two categories: (1) the specific proliferative effects of estrogen and (2) those effects which are secondary to hyperemia. The latter effects can be reproduced by nonspecific hyperemic agents such as yohimbine. However, when they result from the action of estrogen they are due to the acetylcholine-liberating properties of this hormone, as demonstrated by Reynolds.²

In view of the large proportion of the estrous phenomenon in animals which is dependent on hyperemia, it seemed likely that the role of hyperemia was probably even more important in the periodic menstrual bleeding of the human female. Considering the mechanism of this hyperemia, it would presumably also be

under the influence of at least the parasympathetic nervous system. This relationship of the nervous system to uterine hyperemia might readily account for the well known influence of mental, emotional and physical strain on the menstrual history of women. It

TABLE 1.—The Lack of Effect of Prostigmine on Pregnancy in Rats

Number of micrograms of prostigmine per 100 Gm. of body weight injected subcutaneously, on each of the first three days of pregnancy	Approximate Dose Used in Human Beings	Approximate Minimum Lethal Dose
	2.5 5.0 10.0 15.0 20.0 30.0 40.0

Number of rats which had normal gestation periods and deliveries and bore healthy litters.....	1 1 3 1 3 3 0	
Number of rats killed by the dosage used	0 0 0 0 1 2 5	

thus appeared possible that cases of delayed menstruation, now generally ascribed to temporary endocrine dysfunctions, might in fact occur despite normal hormone secretion and be due to abnormally decreased vascular responsiveness. It therefore seemed worth while to attempt to treat such cases by pharmacologic rather than by endocrine means.

METHODS AND RESULTS

The mechanism of the hyperemic action of estrogen suggested the use of acetylcholine. But, since this seemed not without danger, it was decided to potentiate the naturally occurring acetylcholine in the uterine endometrium by inhibiting the cholinesterase with prostigmine methylsulfate, a synthetic physostigmine-like substance which is commercially available.³

Since we proposed to use prostigmine to precipitate the menstrual flow of women in whom this function was significantly delayed, we considered the probability that some women would present themselves in early pregnancy. Although this possibility could be ruled out by history and physical examination in most cases, it was necessary to be certain that the treatment would not disturb an early pregnancy if the diagnosis should be missed. For this purpose a series of freshly impregnated rats was used. The animals were injected on the first three successive days of pregnancy with amounts of prostigmine which varied from doses equivalent to those we wished to use on patients to large doses within the lethal range. The results are summarized in table 1. It may be seen that prostigmine did not terminate the pregnancy in a single instance, even when relatively huge amounts of the drug were given. Those animals which did not succumb to the immediate general effects of the lethal dosage went on to normal gestation periods and deliveries and bore healthy litters.

With the assurance gained from our animal experiments, we proceeded to test the effects of prostigmine on women in early pregnancy, as judged by history, physical examination and a positive Friedman (modification of the Aschheim-Zondek) test. Table 2 shows that the pregnancies were not affected. No untoward or unpleasant, subjective or objective effects of the drug were observed.

Table 3 summarizes the results of prostigmine treatment in cases of delayed menstruation in which early

pregnancy was ruled out by the history and physical examination, supplemented by the Friedman test when necessary. Prostigmine invariably precipitated the menstrual flow. The flow started as soon as half an hour after the injection in one instance. The longest interval between the last injection and the beginning of the flow was seventy-eight hours. The average time which elapsed was twenty-eight hours. In some instances the amount of flow was somewhat heavier than that usually experienced by the patient, though not alarmingly so. With one exception, all the patients reported normal menstruation at their next regular period.

COMMENT

We are aware of the possibility that some of our patients with delayed menstruation might have started to menstruate even if no treatment had been given or if a placebo had been employed. But the invariable nature of our results and the fact that the flow started after an average interval of only twenty-eight hours can leave no doubt that prostigmine precipitates menstruation when it would otherwise not occur. Indeed, from our experience it is possible to assure the patient treated with prostigmine that she will soon menstruate unless she is pregnant. If she fails to menstruate, pregnancy may be diagnosed with the same degree of accuracy as is possible with the Friedman test.

It must be emphasized that this procedure applies only to delayed menstruation in women who have had a normal menstrual history up to the last period. It

be due to lack of vascular response rather than to endocrine dysfunction.

2. On the basis of the physiologic mechanism of estrous hyperemia, women suffering from delayed menstruation were treated with prostigmine. Menstrual flow invariably resulted.

does not apply either to early or to prolonged amenorrhea due to endocrine dysfunction or to local organic changes. For the sake of completeness we have administered prostigmine in a considerable number of cases of the latter types, without the slightest result.

SUMMARY AND CONCLUSIONS

1. The important role of hyperemia in the estrous phenomenon suggested that delayed menstruation might

March Foot.—March foot is a linear fracture through the middle of the shaft of a metatarsal bone appearing without the history of a severe injury. It may occur in the second or third metatarsal bones. The condition derived its name from the fact that it was first noted in army recruits following prolonged marching. Clinically it is characterized by swelling of the soft tissue in the dorsal area with pain and tenderness over the involved bone. The condition is usually associated with metatarsus latus and pes valgoplanus and is sometimes seen secondary to the radical operation for hallux valgus. It is believed to be caused by a mechanical insufficiency in the anterior part of the foot which results in an increased load on the metatarsal bone. In addition, it may be the result of a strain and may occur in civilians as well as in military recruits.—Hauser, Emil D. W.: Diseases of the Foot, Philadelphia, W. B. Saunders Company, 1939.

THE HYPOTHALAMUS

PACEMAKER OF METABOLIC AND
EMOTIONAL RHYTHM

FOSTER KENNEDY, M.D., F.R.S.E.

Professor of Neurology, Cornell University Medical College
NEW YORK

"One gains the impression that, consistently with its primitive place in the evolution of the brain, the hypothalamus contains the mechanisms of the more primitive psychic and emotional reactions. It plays a part in conditioning moods of elation and depression, and their expression in laughter or weeping. It is concerned with reactions of defence, aggression, suspicion, fear, anger, sex. It ignores refinements of decency and convention, if isolated from the control of its better educated instructor the frontal cortex, which seems to exercise an inhibitory influence on its cruder yet vitally important functions. The exact clinical picture evoked depends no doubt upon the exact pattern of the lesion."

This sketch of some hypothalamic functions was written by a neurologic surgeon, Norman Dott. He continued his statement by saying that we possess little knowledge of the detailed anatomic arrangement of hypothalamic mechanism. However, this idea is so much understated as to be hardly true.

As we have seen during the present meeting, the mamillary areas are concerned with sleep, the anterior part of the hypothalamus with the antidiuretic principles and, despite some differences of opinion among physiologists, the local habitation of the instruments controlling carbohydrate metabolism and even sexual activity has been named. It seems, however, that more emphasis has been placed on position and process than on the rhythmic character of process. And I would advance the notion that *not only* vegetative functions are controlled in this primitive area but also their innate systole and diastole. The hypothalamus is a neuroglandular instrument in command of vital rhythm. During the two days of this meeting we have become acquainted with the placement of processes situated in an area one three hundredth part the size of the total brain. Writing this before I hear the sapience of my colleagues, I cannot know whether they will speak of the metronomic function which one can see exerted by this antique middle place. The timing of the organism is placed here, influenced somewhat by its intimate connections with newer and also with older and still more primitive sources of power and feeling. To speak, however, of the signs and symptoms produced by various forms of disease affecting this place would be in a sense only to make a kaleidoscope tortured into pattern of the functions and dysfunctions which have been already described by both physiologists and clinicians, and would be over-repetitious as well.

FUNCTION OF HYPOTHALAMIC AREA

The supreme mystery lies in commonplace phenomena so exquisitely maintained that they excite almost no attention. The regularity of the rhythm of breathing, the constancy of pulse rate, the exact maintenance of body temperature, the beautiful balance of the intake and output of fluid, the cycle of sleep, the integrity of body weight and the imposed periodicity

of the menstrual rhythm—all these ebbs and flows are instrumented primarily through the area which we have been considering. And this integrating mechanism of the diffusely working sympathetic, and the discretely working parasympathetic, systems are linked—and perhaps activated—by hormonal messengers, chiefly from the hypophysis, but stimulated and controlled through the subthalamus to the thalamus and thence to the prefrontal cortex. It is not surely possible that the last arrived chieftain can seriously influence the primitive forces innate in a structure as ancient as the hypothalamus. The rhythms of each individual are innate and are built into the organism. They may seem, superficially considered, to be under the influence of the conscious ego. But so do the Atlantic rollers seem to be made by the wind and the weather. These, however, only change the appearance of the top of the roller. The great wave itself, propagating its energy for thousands of miles across the sea, is really made by another force of which the observer cannot be conscious, namely the rotation of the earth.

While much attention has been devoted to the more easily observed metabolic functions of the hypothalamic area, it would seem proper in now closing our session to ask that more attention be given to rhythmic fluctuations in mood and behavior, and of emotional expression, consequent on stimulation or depression of these areas in a manner as yet not understood. One must remember how Foerster produced the symptoms of acute mania when he set in motion a tumor, pressing from below the walls of the third ventricle. And how in another case, when he wiped blood clot from the surface of the third ventricle walls, manic excitement immediately was produced. In fact, Ranson goes so far as to say that "the fact is no longer doubtful that a manic condition can be produced by mechanical stimulation of the oral part of the hypothalamus in man." And Ranson goes on to say that "the manic symptoms cannot be produced from any other spot, such as the walls of the lateral ventricle or the head of the caudate nucleus." On the other hand, interference with the collicular region and the posterior part of the hypothalamus is followed by unconsciousness and sleep.

We have elected at this session to confine our attention to one small area out of the entire neural mechanism. Such specialization makes for accuracy in one direction. It is, however, a thoroughly artificial approach and inadmissible as an approach to the understanding of the total integration of these structures and functions.

DISEASE OF THE HYPOTHALAMUS

Many observers, as Penfield, believe that "in the thalamus and on the hypothalamus lies the highest representation of the vegetative nervous system." We know that, by the subthalamus, the hypothalamus is linked structurally and functionally with the corpora striata; with the hypophysis by fibers originating from hypothalamic elements, and that the anterior nuclei of the thalamus are linked to the gyri cinguli above and, below, to the mamillary nuclei by the bundle of Vicq d'Azyr; so we must appreciate that hypothalamic disease will paint pictures many of which are not susceptible of being artificially thrust on the hypothalamus itself for explanation. Further, in an area where sympathetic and parasympathetic functions are both represented in their enormous variety we discover stimulating clinical patterns of dysfunction not ordinarily associated together in our minds. For instance,

we readily accept amenorrhea as part of the picture of abnormal obesity in young women. We somehow see immediately that the same lesion has produced both of these two symptoms, but we do not so readily see that the fluctuations in body weight, the sleeplessness and the amenorrhea of a young woman with cyclothemia are caused by the same lesion that has produced her recurrent manic behavior and mood. Indeed we constantly are asking ourselves "Did the suppression of her menses cause her mental breakdown?" instead of perceiving that the large probability is that the break in the rhythm of her menses has been produced by the same abnormality in structures and in function that has caused the break in rhythm of her emotional life. Mutual antagonisms in functional activity emerge from lesions in this place. For instance it has been shown that solution of posterior pituitary opposes the action of insulin, and it would seem that pitressin cannot control diabetes insipidus in the presence of sleep. And high blood sugar associated sometimes with acromegaly can hardly be influenced at all by insulin and diet. And why do depressed cyclothemetic patients experience depressional depths almost inversely as the square of the distance from sleep? We try to make them sleep but, when they do, for some hours afterward they're always the worse for it. Ordinarily they have a diurnal rhythm, much worse on waking in the morning; many of them state that they feel fog lifting from their spirits and minds in the late afternoon and often they are entirely normal throughout the evening. But such people, should they sleep in the afternoon, do not experience their usual betterment in the evening. A like paradoxical antagonism is seen in the production of narcolepsy and cataplexy by a positive emotion like laughter and surprise producing the negation of sudden morbid sleep or muscular tonelessness and falling. Again may one stress how much the hypothalamus is concerned not only with emotional expression (which may be mainly thalamic) but with mood? And it is no accident that postencephalitic children are hypomanic.

CAUSATION

Not all hypothalamic syndromes are due to acquired disease, such as injury, infection or the formation of tumor. One of my patients suffering from severe diabetes insipidus had an interesting family history. Her mother and aunt and her mother's mother have all been extraordinarily obese. The grandmother weighed 230 pounds (104 Kg.) and also her father, of 6 feet 4 inches (193 cm.), 368 pounds (167 Kg.). The other children in the family, aged 9 and 11 years, weighed respectively 128 (58 Kg.) and 118 pounds (53.5 Kg.). My patient, aged 17, three years ago weighed 165 pounds (75 Kg.); there developed severe polyuria and polydipsia and her weight dropped to 98 pounds (44.5 Kg.). Her basal rate was minus 18. There has been no evidence of neoplasm and I believe that she suffers from a familial hypothalamic-pituitary defect. Another girl, aged 20, however, after the removal of a severely infected wisdom tooth became subject to sudden attacks of uncontrollable drowsiness, which she noticed came upon her on anger and laughing, especially during the morning hours. These attacks of sudden sleep were often replaced by attacks of her knees giving way when excited, angered, surprised or suddenly amused. The same weakness has occurred in the arms. She has a sudden sensation of intense weakness at these times but is usually able to protect herself by holding on to a table or, as she said lately,

clutching the railing that she had been leaning against when excited by a hockey game. Sometimes on laughing she experiences a sensation of darkness coming from the back to the front of the head followed by sudden falling, in which she has occasionally hurt herself. She has also periods of enforced immobilization, during which she can't lift a hand by will or move a foot or speak. These may last half an hour or an hour and sometimes in them she falls asleep for ten minutes. Emotion triggering morbid sleep put one of my patients in an impossible position when he suddenly slept with snores on kissing a girl in a taxi cab, and a patient with acromegaly always yawned in the middle of his own speeches, an involuntary reflex and no sign of grace.

ILLUSTRATIVE CASES

It would be commonplace to speak before such a body as this of clinical phenomena which have been so often viewed by us all. For instance, one of my patients at Bellevue with tumor involving the floor of the third ventricle producing polydipsia, polyuria, obesity and impotence of long duration had a psychosis indistinguishable from dementia paralytica; a child with supra-optic glioma characterized by progressive blindness and intense diabetes insipidus, which could be modified by the use of pitressin. Such symptoms have been well recognized and have been much explored already at this meeting. I have seen, however, four families, unrelated to one another, all presenting in the majority of their members clear signs of abnormal pituitary function. In these four families, instances of Froelich syndrome, gigantism, acromegaly, mild diabetes insipidus, occurred; in all four families as well there were two or more cases of manic-depressive psychosis, so that I came to relate in my mind these conditions together. However, not only is manic-depressive psychosis found in frequent association with hypophyseal and hypothalamic abnormality but various behavior problems, lying, stealing, arson and temper tantrums, have occurred in young people under my observation, accompanied by functional hypothalamic "organic" signs more frequently than they do in persons physically normal. Such instances are important in the consideration of body-mind relationship.

In this regard the disturbance of vegetative function in hypothalamic encephalitis can hardly be overstated; not only have such cases been difficult to differentiate from so-called pure psychoses but some of them have furnished, by the disruption of vital rhythm, valuable data for a comprehension of neurotic and psychotic phenomena on a physical rather than on a purely emotional or psychic basis.

H. G., a man aged 21, served as a private in the United States Marines during the last war and was supposed to have disintegrated mentally following an alleged attack of influenza in London during the month after the armistice. He was placed in an excellent hospital for mental diseases for about eight months after his return home. The diagnosis was dementia praecox, at that time still the fashionable name for schizophrenia. The clinical picture seen in the spring of 1921 was sufficiently confusing; a young man of splendid physique carried his height of 6 feet 2 inches (188 cm.) with a pronounced stoop, an acquisition of his illness. Without syphilis the pupils were distinctly sluggish to light; the right side of the face flattened in its creases, and there was a fine aspic jelly-like, but definite, nystagmus on lateral conjugate deviation of the eyes to the right or left. There was pronounced tremor in the extended hands. He had lost more than 30 pounds (13.6 Kg.) since his illness; except for the absence of the abnormal reflexes, great increase in the arm, knee and ankle reflexes and involun-

tary shivering movements of the pectoral muscles, nothing more of pathologic interest could be made out in the sensorimotor system. He suffered, however, from severe nocturnal insomnia, rarely sleeping more than two hours before dawn, after which he would usually waken and again grow drowsy and perhaps sleep three or four hours before noon. Whether he slept or not, during the first part of the day he was utterly inert and exasperated by his inertia. He had the utmost difficulty in accomplishing through defective will power and indecision simple acts, such as shaving, dressing or bathing. He agonized for hours in futile efforts to write a short note or keep an important engagement during this early part of the day. In his mental attitude there was no trace of negativism; he desired passionately to do those things which he could not do at that time but which later in the day he often could do with relative ease. There was a distinct resemblance between his inability to perform acts to the completion of which he was urged by will, lacking the stronger adjuvant of emotion, and the palsy of purely voluntary movements in midbrain encephalitis of the parkinsonian type—palsies so often abolished by emotional stimulation. He complained frequently of "numb attacks" during which he felt very cold and in which he shivered and his teeth would chatter like a man with a rigor. During these attacks, even in July weather, his rectal temperature was always subnormal, on several occasions being 97 F.; and on his skin were large patches of goose flesh which covered a third of the body area at a time and which, under observation, changed their position like a breeze over still water.

In the same general period but not necessarily and indeed rarely at the same hours, he had attacks of disturbed breathing rhythm of from a quarter to half an hour's duration. During these attacks he felt as though he could not fill his lungs with air and breathed with all his accessory respiratory muscles from fifty-six to sixty-four times a minute. At other times he experienced what seemed like a spasm of the laryngeal muscles and breathed more and more stertorously and ineffectively so that the lips were cyanosed and the eyes protruded. Phenomena such as these have appeared at times in hysteria, and various physicians had considered them hysterical in this case. This explanation, however, could not account for the patient's abnormal thirst for ice water. He consumed for a period of eighteen months between fifty and sixty tumblers of water every twenty-four hours and had proportionate polyuria.

An analysis of the initial illness in December 1918, which he had always considered influenza, revealed the only symptom to have been severe headache and intense sleepiness by day and by night. Two negative features of value, however, were that he had had no feeling of fever and that he had never reported sick to a medical officer. It is highly unlikely that this could be true of any youthful patient with the influenza which was prevalent in London at the end of 1918. Furthermore, after three or four weeks sleepiness disappeared during the night time and was present only by day, a reversal of the sleep mechanism sufficiently familiar to all students of epidemic encephalitis.

The patient's symptoms during the last eight months of his illness gradually improved to almost normal, with little or no morning inertia, no difficulty with respiration and no rigors; polydipsia was reduced to an intake of only three quarts of water a day.

A boy of 14 had a similar polydipsia and polyuria, tremors in the upper extremities, excessive salivation and similar distressing paroxysmal attacks in which breathing was exceedingly rapid, labored and difficult. At these times there was great emotional distress and suffering. This boy had acute encephalitis in January 1920 with visual disturbance, diplopia, fever and excessive insomnia; this was followed for many months by apparent recovery and was gradually succeeded by a rhythmic incessant cough and stammering and thereafter by the distressing symptoms already described.

Another patient, a woman of 28, developed severe hypertrichosis of the face and arms following encephalitis. Great increase in body weight has been a fairly common sequel of that disease as it is of neoplasms interfering with the third ventricle floor. It happens that this disturbance of metabolism was seen in our series mainly in female patients. One patient within half a year gained over 150 pounds (68 Kg.).

Rhythmic movements, breathing irregularities and eccentric stations may be attributed to disturbance of the toning mechanism of muscles.

Five patients, all with an early parkinsonian syndrome, had stammering as a sequel to their illness. In one of these cases the disorder accompanied a severe relapse precipitated by a fright occurring two months after the onset of encephalitis. In the other instances stammering appeared from three months to two and a half years after the first symptoms and without any psychic shock. Three patients had rhythmic movements. An encephalitic patient had from the onset of her illness bilateral rhythmic action of the masseters, which gave a champing "subway" movement to the jaws. This was constant during the waking hours and, with her immobile facies and unwinking stare, resembled remarkably the breathing movements of a fish: perhaps a return to an earlier facial aspect!

These movements occurred about once in two or three seconds, were not under control of the will nor varied by attention or emotion and could not be inhibited by any voluntary use of the involved muscles. Their maintained rhythm distinguishes them to some extent from habit spasms, some of which, however, have a striatal origin. I think many cases of hysteria may be in mechanism a retreat by the personality from a cortical to a more primitive reflex level of motor expression and sympathetic discharge, so that hysterical episodes necessarily have the striatal and hypothalamic pattern and color imposed on them by the physiologic mechanism through which they find expression.

One patient had very irregular breathing—both in depth and in rate—accompanied by curious noises which occurred only during sleep. On the other hand, a narcoleptic with lingual dystonia and almost unintelligible speech in his sleep talks fluently and normally well. S. J., fifteen months after apparent total recovery from encephalitis, had a parkinsonian relapse, accompanied by attacks of rapid deep breathing, profuse sweating, lacrimation, salivation and venous congestion of the face. These increased in frequency and at last continued throughout the waking hours, causing intense fatigue. Emotion would initiate them, but when started they could not be stopped until their course was run—usually in a minute or two. There was never any feeling of dyspnea but a sensation that he could not possibly fill the lungs and an intense desire to fill them.

One patient had recurrent vomiting which persisted for three weeks. Several times a day, with or without food in the stomach, expulsive movements occurred; the vomiting was probably in morbid process analogous to the rhythmic movements and breathing spasms just described and also analogous to the hiccup seen in certain cases of encephalitis. Such visceral perversions, however, may be due to parasympathetic explosion. A 12 year old boy had acute anteropulsion of the trunk, so that he looked backward through his legs as Peter Pan looked at the bears. He could walk only by splinting his torso upward by his arm, held rigid on his knee. Another boy, aged 15, maintained when sitting or standing a deviation of the trunk to the left so that the upper part of the trunk was almost at right angles to the pelvis. Neither patient ever fell. At a certain point the active pull would cease, movement would end and the attitude would be maintained. This was a clinical replica of the experiments of Ecker and Brookney and Gerard in which stimulation of the posterior part of the posterior area of the third ventricle wall produced concavity of the spine to the ipsilateral side.

Limitation of parkinsonian symptoms to the upper extremities and to the face was observed twice. This leads one to the probability that individual centers in the corpora striata rerepresent individual spinal segments.

The rich connection between the basal olfactory regions and the hypothalamus account for the almost constant appearance of intense fear referred sickeningly to the pit of the stomach in uncinate fits and even in the dreamy mental states of temporosphenoidal origin. And there is sound structural basis for the fact that persons passing through morbid internal depressions have perversions or entire abolition of appetite, taste

and smell. The severe mental and emotional depressions in adolescent girls and young women which we wrongly call *anorexia nervosa* are explicable in these terms also.

A well known physician under my care after a short acute attack of epidemic encephalitis, characterized typically by stupor, diplopia and slight continued fever, experienced an inability to sleep more than four hours in the twenty-four; he had intense motor restlessness, constant elation, a passion for midnight cabaret parties and bursts of talking and walking lasting for hours at a time, which he stated he could in no way control. This manic phase lasted eight months and was followed by a year of depression, slowed activity of mind and body, and occasional irritability. The manic-depressive psychosis ran its course after about two years from the beginning of his illness and then allowed the patient to resume his normal rather sedate and conscientious personality.

COMMENT

I have described at some length my first case of disturbed vegetative function in the course of epidemic encephalitis, but since that time many instances of dementia praecox-like pictures came to our Neurological Department at Bellevue Hospital and to the Neurological Institute. There have been patients with catalepsy, spontaneous or provoked, with fixed bodily attitudes of bizarre character, with altered personalities fluctuating between docility and paranoid opposition; patients with stereotyped and reiterated words and phrases with persistent closure of the eyelids and retention of urine and feces; garrulity alternating with mutism; ethical defects with flight of ideas and euphoria, and at times markedly antisocial trends. The milder cases, however, presented fantastic neurasthenic symptoms, an agitated anxiety, a loss of confidence and exaggerated shyness and self consciousness with feelings of embarrassment, unreality and much slow mindedness.

Some patients suffered from lack of spontaneity and disappearance of all voluntary activity. The emotional tone was apathetic so that, growing disinterested in business, family or friends, the patient ceased to bother about his condition from sheer apathy and mental powerlessness. Mental asthenia may coincide with hallucinations or delusions of a paranoid character, but more usually there is an irritable nervousness toward himself and an inert indifference toward his environment, which for him has become a gray monochrome without significance or form. Such persons usually are sexually impotent, but one sees many instances of greatly increased libido accompanied at times by sadistic behavior. However, in neurology there is happily discerned an inevitability in clinical symptoms emanating from lesions of structures with known physiologic functions. The sympathetic functions after all are centrifugal and centripetal; by their joint action is determined the mood of the organism and they also control smooth muscle contraction and glandular secretion. Lesions therein give rise to dissociation between emotional and voluntary activity of muscle and to alternation in vasomotor control and respiratory rhythm; to emotional mimicry, tachycardia and spastic laughing and crying. Lesions of the hypothalamus and floor of the third ventricle give rise to glycosuria, salivation and increased sweating with maybe pathologic sleep. Tonus in general is under the high control of part of the striatum, and changes in the striatum can give rise to plasticity to the point of catalepsy with tremors and rigidity. Automatic associated movements also are under striatal government: it may be that in paralysis agitans we have an antique expression of both facial

emotion and bodily posture: a phylogenic retrogression—man becomes ape.

We have heard the results of physiologic experiment in these brain areas; in epidemic encephalitis these areas are the seat of perivascular round cell infiltration. This is found around the aqueduct also, together with fat accumulation in the ependymal cells of the lateral ventricles and in the tuft cells of the choroid, and throughout the walls and floor of the third ventricle.

I submit that we must correlate these lesions with disorders of personality as we correlate lesions of the thalamus and striatal bodies with athetosis, tics and tremors. By so doing we shall take a notable step toward developing knowledge of the metabolic rhythm and may even lay the foundation of the science of the pathology of emotional and energetic drives.

PHOTOSENSITIZATION BY
PHENOTHIAZINE

FLOYD DeEDS, Ph.D.

ROBERT H. WILSON, Ph.D.
AND

J. O. THOMAS, A.B.

SAN FRANCISCO

Among the more promising organic insecticides developed as substitutes for lead and arsenic is phenothiazine. When field tests were made on the practical application of this insecticide for control of the codling moth, some of the men applying a spray containing the compound complained later of intense itching, irritation and reddening of the skin. In some cases the reactions were severe, being accompanied by edema and secondary infection in areas of intense hyperemia, and required hospitalization. Attending physicians have diagnosed the reaction variously as sunburn, chemical burn and dermatitis.

In sharp contrast to these reports is the fact that several members of our laboratory staff have worked with phenothiazine for several years on an investigation of its toxicity and have experienced no cutaneous reactions. Applications to the forearms of phenothiazine mixed with hydrous wool fat to promote absorption produced no irritation. In an investigation of the efficacy of phenothiazine as a urinary antiseptic,¹ a series of ninety-two patients were given doses of the compound orally, ranging from 3.12 to 42.9 Gm. for the entire period of treatment, but no undesirable cutaneous reactions were produced.

SUGGESTED EXPLANATION OF CUTANEOUS
REACTIONS

In view of these apparently contradictory facts, an explanation of the toxic reactions observed in orchard workers was sought on the basis of the known fate of phenothiazine in the body² and the environmental conditions of the workers.

Phenothiazine, after oral administration, is oxidized to the reversible oxidation-reduction system thionol-leukothionol. The products excreted in the urine are unoxidized phenothiazine in some soluble form, thionol,

leukothionol, and leukothionol in some chemical combination from which it is readily liberated in acid reaction. In the present connection the reversible oxidation-reduction system thionol-leukothionol is of interest. Thionol is closely related to thionin (Lauth's violet) and to methylene blue, as shown in the oxidation-reduction equations employing structural formulas.

These three oxidation-reduction systems have in common a characteristic which may have some bearing on the problem at hand. In each case, the leuco form kept in solution under strictly anaerobic conditions is photosensitive. On exposure to sunlight, the leuco form is converted to the oxidized component. Likewise the porphyrins and chlorophyll are oxidation-reduction systems in which the leuco form is photosensitive. These systems, including thionol as shown later, sensitize individuals to sunburn. Whether photosensitivity of the leuco forms is essential to the production of sensitization to sunburn cannot be stated, but it is interesting to note that the two phenomena are often associated. In addition to these systems other photodynamic sensitizers are known such as erythrosin, rose bengal, rhodamine, anthracene derivatives, acridine dyes, quinine and hypericin. Still others produce sensitiza-

tion to sunburn indirectly through their ability to produce porphyrins by an action on the blood.

Examination of a urine sample obtained from an orchard worker who experienced a cutaneous reaction associated with the spraying of phenothiazine showed the presence of thionol and leukothionol. The presence of these two oxidation products of phenothiazine in the urine proves that phenothiazine must have been absorbed into the body from the skin, possibly by swallowing saliva contaminated with phenothiazine, or more likely from the respiratory tract after inhalation of phenothiazine spray.

Orchard workers applying phenothiazine sprays are subjected to environmental conditions contrasting sharply with those of laboratory workers and the ninety-two patients observed by us.¹ The orchard worker is exposed considerably to sunlight and on warm days may strip to the waist, especially in areas such as the Yakima and Wenatchee valleys of Washington. The exposure to sunlight and heat, the demonstrated presence of thionol in the urine indicating absorption of phenothiazine, and the possibility of a photodynamic effect provide a rational explanation of the undesirable cutaneous reactions in the orchard workers exposed to phenothiazine spray. This theory was subjected to the following tests:

TESTS FOR PHOTSENSITIVITY

We served as experimental subjects in the following manner: The volar surface of one forearm of each subject was divided by drawing an ink line from the

elbow to the wrist, and the area on one side of the line was painted with a 2 per cent alcoholic solution of phenothiazine so as to leave a thin, even deposit of phenothiazine after evaporation of the alcohol. The arm was then exposed to the radiation of a General Electric No. S-1 sun lamp at a distance of 30 inches (76 cm.) in such a manner as to give three areas of different exposure time at right angles to the ink line. This procedure permitted a determination of the exposure time necessary to produce a definite degree of hyperemia in each subject and at the same time show whether the area coated with phenothiazine was more or less susceptible than the corresponding control area. Two subjects (F. D. and R. H. W.) took 0.75 Gm. of phenothiazine in capsules in three divided doses of 0.25 Gm. The third subject (J. O. T.) took capsules of thionol in lieu of phenothiazine. Approximately twelve hours after taking the last dose each subject exposed the volar surface of the other forearm to the radiation of the sunlamp under similar conditions.

The results of these tests may be summarized as follows: The control arm of each subject clearly demonstrated that the area coated with phenothiazine was markedly protected against the development of hyperemia even with the longest exposure. Accordingly it must be concluded that, under the conditions, phenothiazine applied locally caused neither irritation nor predisposition to sunburn. Irradiation of the other arm after oral administration of either phenothiazine or thionol resulted in a sensitization to sunburn as judged by an increased hyperemia in areas receiving the same amount of radiation as the corresponding areas on the control arms. It must be kept in mind that the effects observed necessarily represented a hyperemic area developing about eighteen hours after that on the control arm.

The results obtained on subject R. H. W. are shown in the reproduction of the photograph. To accentuate the results for purposes of reproduction the photograph was made with color blind film so as to insure darkened areas where hyperemia existed. This procedure resulted in the reproduction of freckles as black spots. The ulnar aspect of the volar surface of the left arm shows the lack of hyperemia due to the protective action of locally applied phenothiazine. The radial aspect of the same arm shows three areas of hyperemia due to three different exposure times. The dark band across the volar surface of the right arm shows the more intense hyperemia produced after oral administration of phenothiazine. The exposure time was the same as that for the area of most marked hyperemia on the left arm.

These results strongly suggest that the undesirable reactions experienced by orchard workers when applying phenothiazine sprays are not due to a local irritant action of phenothiazine. More probably they are due to a systemic reaction of the individual to sunlight traceable to a photosensitization produced directly or indirectly by the presence of the oxidation-reduction system thionol-leukothionol in the tissues resulting from the oxidation of absorbed phenothiazine.

If this is true, several remedial measures suggest themselves: 1. Prevent absorption of phenothiazine by wearing a suitable mask. 2. Eliminate undue exposure to sunlight by wearing suitable clothing. 3. Protect exposed areas from sunlight by protective coatings such as zinc oxide ointment or even phenothiazine itself. It should be mentioned that our experiments were made with pure phenothiazine and permit no conclusions regarding the action of possible impurities or other

ingredients in the spray. Lastly, a victim of such photosensitization should, in addition to any soothing local application advised by the attending physician, remain in a dimly lighted room and drink liberal quantities of water to promote diuresis and thereby facilitate excretion of the thionol.

With regard to the mechanism of the photosensitization, two possibilities suggest themselves: The thionol may produce sensitization per se in the same sense that coproporphyrin does or it may give rise to an increased porphyrin content of the blood, as is probably the case with certain other sensitizing agents. Attempts made by us to determine whether or not oral administration of phenothiazine leads to an excretion of coproporphyrin were inconclusive. The method employed for the detection of coproporphyrin in urine depends on observation of the absorption bands in 25 per cent hydrochloric acid. Unfortunately for such identification, thionol

Photosensitization produced by orally administered phenothiazine (subject R. H. W.).

is excreted in the urine, and the absorption bands of thionol in 25 per cent hydrochloric acid are so nearly the same as those of coproporphyrin that we were unable to differentiate the two substances with our spectroscopic.

SUMMARY AND CONCLUSIONS

1. Oral administration of phenothiazine results in the excretion of the reversible oxidation-reduction system thionol-leukothionol.
2. Leukothionol is photosensitive and, under anaerobic conditions, is oxidized to thionol when exposed to sunlight.
3. Oral administration of phenothiazine to two persons and thionol to one person resulted in a demonstrable sensitization to radiation.
4. It is suggested that the cutaneous reactions of orchard workers applying phenothiazine sprays are due to photosensitization and not to local irritation by phenothiazine.

SUPPRESSION OF ISO-AGGLUTININS

AND THE SIGNIFICANCE OF THIS PHENOMENON IN SERUM TRANSFUSIONS

SIDNEY O. LEVINSON, M.D.

AND

ANNY CRONHEIM, M.D.

CHICAGO

Universal donors (group O) are used very commonly for patients belonging to other blood groups. There is a theoretic risk of incompatibility from the use of universal donors whose serum iso-agglutinins are of high titer. Gesse¹ collected forty-six instances of incompatibility resulting in twenty deaths following the use of blood from a universal donor. On the basis of agglutinin titrations he found that more than 30 per cent of universal donors have an agglutinin titer over 1:32, a titer which he considers dangerous. It is obvious that practical experience does not confirm these fears. Vast numbers of transfusions from universal donors are given with complete safety. The rare occurrence of an incompatibility reaction is more apt to be due to inaccurate blood grouping from the use of weak typing serums and weak agglutinin. Erroneous blood grouping is a more frequent cause of incompatibility.²

Why can serum containing iso-agglutinins against the recipient's cells be administered safely? Dilution of the agglutinins³ is not an adequate explanation. Wiener⁴ points out that absorption of the donor's agglutinins by the tissues of the recipient⁵ and neutralization by the recipient's own serum will also tend to prevent a reaction. However, there are no quantitative studies on this absorption effect. The significance and degree of agglutinin suppression has not received sufficient attention or emphasis.

Recent developments in the use of serum or plasma for transfusions focus attention on the importance of agglutinin absorption. Two reports⁶ on the use of plasma transfusions comment briefly that no typing or compatibility tests were performed and no reactions were observed. No explanation, however, is offered for the fact that compatibility tests may be omitted with impunity.

Large amounts (from 100 to 1,000 cc.) of pooled human serum have been administered intravenously by us in the past ten years in more than 1,000 instances, without any evidence of incompatibility. We have always employed pooled human serum (each pool made up of the serum from thirty to fifty different specimens

of blood). We have observed that large pools of serum never showed rich agglutinin content, whereas many of the individual serums that made up the pool possessed a high agglutinin titer.

We determined to study the agglutinin absorbing action of serum. The tube-slide method was employed. Blood cells were suspended in 0.85 per cent sodium chloride solution. Equal amounts (0.5 cc.) of serum or diluted serum and suspended cells were mixed in a test tube, and after due agitation a sample was removed with a glass rod, placed on a glass slide and examined under a microscope periodically up to thirty minutes after preparation. All the results reported at this time were obtained at room temperature, with controls in the incubator and refrigerator.

Two rows of serum dilutions were set up. In the first row the test serum was diluted with physiologic solution of sodium chloride, while in the second row the test serum was diluted with serum of the opposite group. Thus when group A serum was employed as the test serum, group B serum was used for diluting purposes against the saline dilution as control. When group B serum was used as the test serum, group A serum was the diluent against a saline control. Nineteen serums were tested, as summarized in the accompanying table. The average agglutination observed with the controls of serum diluted with saline solution was 1 to 20+. The average agglutination in the serum diluted with serum was 1 to 2. Two of the twenty serums which we used were very weak in agglutinins,

at present. Neutralization of agglutinins by both tissue and serum of the recipient provides a wide margin of safety in protecting the recipient's red blood cells from the infused agglutinins. This mechanism of agglutinin absorption not only accounts for the practicability of using universal donors but also explains the safety of serum or plasma transfusions without preliminary blood grouping and compatibility tests.

Since there is neutralization of agglutinins in vitro when different groups of serums are mixed, it is recommended that serum or plasma prepared for transfusions should be made up of pools containing all blood groups, resulting in a final low agglutinin titer fluid.

Clinical Notes, Suggestions and New Instruments

RECURRENT HERPES OF THE CORNEA AND RECURRENT HERPETIC FEVER RESULTS OF TREATMENT WITH SMALLPOX VACCINE

PERK LEE DAVIS, M.D., PHILADELPHIA
Assistant Attending Physician, Philadelphia General Hospital

There are many diseases caused by viruses. They occur in plants, for example the mosaic disease in tobacco and the rosette disease in wheat. They are found in birds as in parrot fever and in animals as in equine encephalomyelitis, rabies and foot and mouth disease, which types may also affect man. In man there are many infectious fevers caused by these virus agents. Among these may be mentioned smallpox, measles, chickenpox, epidemic influenza, infantile paralysis, encephalitis, benign lymphocytic choriomeningitis, herpetic fever, herpes zoster and the common cold.

Although recovery from many virus diseases gives an immunity which lasts for years, it is not constant. It is well known that the common cold, herpes labialis and influenza do not protect the individual from subsequent attacks.

All viruses are intracellular parasites, and a number of them give rise to "coccoid bodies" within the cells which they infect. It has been shown that the number of these bodies is a fair index of the infectivity of a virus. These inclusion bodies, or Lipschutz granules, are within the nuclei of the epithelial cells of all herpetic blisters. They bear a striking resemblance to the Guarnieri bodies in smallpox, which are situated in the protoplasm of the cells. Since vaccinia virus protects individuals from smallpox, it was thought that it might be useful in resistant herpetic conditions.

This paper is concerned with the results of treatment with smallpox vaccine of three patients with herpes of the cornea and eleven patients with recurrent herpetic fever. These fourteen patients were seen in private practice, in the wards of the Philadelphia General Hospital and in the Barton Dispensary of the Woman's Medical College Hospital. Since the results have been uniformly successful in all fourteen cases, only one case of each type will be described in detail. Suffice it to say that, except for minor details as to the duration and frequency of the condition and the number of vaccinations necessary, they were all essentially similar. The treatment seemed to be simple, effective and dramatic in its results.

REPORT OF CASES

CASE 1.—A man aged 44 in 1925 complained of a herpetic ulcer in the left cornea which had persisted for six weeks. This attack was preceded by a severe herpes labialis which had been present for two months before the corneal lesion developed. From 1925 to 1930 he had had three similar recurrences of herpes labialis followed by herpes of the cornea and subsequent ulceration. The last ulcer in 1930 persisted for four months, with continuous herpes of the lips. At this time he was under the care of a prominent ophthalmologist, who had had various presumptive foci removed. The patient then remained well for

so that no agglutination occurred in the saline dilution beyond 1 to 3. One serum was very rich in agglutinins, agglutinating cells in a saline dilution over 1 to 80. On the other hand, in two instances in which serum was used as a diluent of the agglutinating serum, no agglutination could be observed in the lowest dilution of 1 to 1. In seven instances in which serum was used as a diluent, no agglutination was observed beyond a 1 to 1 dilution, and in only one instance was there agglutination seen in a dilution of 1 to 6.

COMMENT

The experiments described demonstrate clearly the agglutinin neutralizing action of serum. This neutralizing property of serum is aided by a like property of all the body cells. This matter is under investigation

more than five years, but in October 1936 a herpetic lesion developed on the face. Since this manifestation always preceded involvement of the eye by about two months, he consulted a dermatologist. However, in fifteen weeks an ulcer developed on the left cornea. Tuberculin tests done at this time gave negative results. He was then seen by the ophthalmologist, who reported a superficial keratitis covering the pupillary area with branched vessels at the limbal margin. He responded slowly to local eye treatment. He was well from April until September 1937, when another herpetic lesion developed involving the lips and face, followed by a herpetic ulcer of the left cornea. Several allergists studied him and reported that his reactions to tests would ordinarily be regarded as negative but felt that food sensitivity was a factor, so banana, grapefruit, chocolate, apple and tomato were interdicted. Sinus studies showed cloudiness of the antrums and the ethmoids. Operations on the sinuses and a tonsillectomy were done. In spite of the diet and the operations there was a recurrence in November 1938. His family physician referred him for study. The patient stated at this time that the present lesion on his lips and face had been there for two months and had been refractory to local treatment. He stated that because of the usual sequence an ulcer of the cornea would be expected to occur almost any time. He was profoundly concerned because he was always incapacitated for from two to four months, and from an economic standpoint he had sufficient cause for worry.

Except for the obvious lesions on the lower lip and chin the physical examination was objectively negative. The prostatic smear yielded negative results. Laboratory examinations of the blood, spinal fluid, urine and feces gave negative results. The serologic reaction for syphilis was negative.

He was vaccinated with freshly procured vaccinia virus. The vaccination was repeated at ten day intervals until he had been vaccinated four times. The first, the third and the fourth vaccinations were takes. Fifteen days after the initial vaccination the lesions on the lip and the chin were almost completely resolved. This was the first time since 1925 that a corneal ulcer had not followed the original herpetic lesion. He has been on a regular diet without any food restriction, has been seen every month for a year and has been symptom free. He has gained weight and feels stronger.

CASE 2.—A man aged 30, seen in the service of Dr. Hobart A. Reimann, Philadelphia General Hospital, complained of chronic fatigue and loss of weight for five years. There had been a mild diurnal fever to 100 F. for this period. He complained of pains in his legs and stated that his entire body ached. The most marked feature had been the constantly recurring fever blisters involving the face, lips and nose, which had been most severe since early December 1938. Since this time his weakness, body pains, weight loss and lethargy had been more profound. He had lost 20 pounds (9 Kg.) up to the time that he was admitted in March 1939. On further questioning the patient stated that for the past five years and particularly since November 1937 he had had recurring attacks of herpes of the nose, lips and face, with pains in his back and severe bone pains every month or six weeks. His most recent attacks had been five weeks and two weeks previous to admission.

The physical examination was essentially negative. The blood pressure and pulse rate were normal and showed no orthostatic abnormality. Roentgenographic investigations of the chest, gastrointestinal tract, colon and genito-urinary tract were negative. Laboratory examinations of the gastric contents, feces and urine were negative. An estimation of the blood chlorides, sugar and urea was within normal limits. The serologic tests for syphilis were negative. Repeated examinations of the blood for malarial parasites were negative. The erythrocytes numbered 3,100,000 and the leukocytes 2,550 per cubic millimeter of blood. The differential smear showed 44 per cent polymorphonuclear neutrophilic leukocytes and 66 per cent lymphocytes. The hemoglobin was reported to be 58 per cent of normal. The basal metabolic rate was minus 12. The electrocardiographic tracings were normal. The temperature record showed a mild diurnal rise of fever from 98 to 100 F., with a proportional increase in the pulse rate.

He received six vaccinations with ordinary smallpox vaccine at fourteen day intervals, and all of them were takes. The patient gained 10 pounds (4.5 Kg.) in three weeks. He felt much stronger and the feeling of ennui disappeared. The fever subsided completely in six weeks. When last seen in November 1939 he was 32 pounds (14.5 Kg.) heavier than he had been. He stated that he never felt better.

COMMENT

An immunity relationship between herpes simplex and smallpox and chickenpox was suggested early in 1927.¹ Schmidt² used the herpetic vesicle fluid to vaccinate eight patients with recurrent herpetic infection, with good results. This method is probably more specific, but if extreme care is not taken the danger of infection is increased. Foster and Abshier³ treated thirty-five patients who had herpes simplex with smallpox vaccine, with only five recurrences. They found that the course of the eruption was decreased in every instance and that immunization to further attacks occurred. Brain⁴ believes that the effectiveness of smallpox vaccine in these cases is purely a nonspecific response. Reimann⁵ believes that the effect is probably a combination of specific and nonspecific factors.

The author heartily recommends the use of smallpox vaccine in the treatment of recurring herpetic infections. It seems to work best if used every ten to fourteen days for from four to eight times. This method has been employed with success and has proved to be safe, efficient and effectual.

SUMMARY

1. Smallpox vaccine was used in the treatment of fourteen patients, three with recurrent herpes of the cornea and eleven with recurrent herpetic fever, all with uniformly good results.

2. Ordinary smallpox vaccine is a reliable, safe, efficient and effectual means of treating herpetic conditions.

ARTERIOSCLEROSIS OF THE RENAL ARTERY ORIFICES WITH SEVERE HYPERTENSION

CHARLES F. STEWART, M.D., NEW YORK

In a recent discussion of experimental hypertension Goldblatt¹ stated that "during the past year, in a few cases of hypertension without renal arteriosclerosis, severe sclerosis and narrowing of the orifice or lumen of the main renal arteries or the lumen of the larger extrarenal branches, obviously sufficient to cause renal ischemia, have been observed." Leiter² reported a case of hypertension believed to be due to sclerosis of the main renal arteries (case 2). The patient's blood pressure varied from 240 to 180 systolic and from 160 to 88 diastolic; the kidneys were very small, one weighing 41, the other only 22 Gm. The glomeruli of the left kidney were hyalinized and numerous tubules were atrophied and obstructed. The main renal arterial branches had an extremely thickened, cellular and fibro-elastic intima; the internal elastica was degenerated. The medium and smaller arteries were the site of extensive degeneration of the elastica and in some of the arteries a new media had developed with a new internal elastic membrane. There was subendothelial

Drs. Walter W. Palmer and Allen O. Whipple gave the author permission to transcribe the clinical records.

1. Goldblatt, Harry: Experimental Hypertension Induced by Renal Ischemia: Harvey Lecture, May 19, 1938, Bull. New York Acad. Med. 14: 523, 1938.

2. Leiter, Leo: Unusual Hypertensive Renal Disease? 1. Occlusion of Renal Arteries (Goldblatt Hypertension); 2. Anomalies of Urinary Tract, J. A. M. A. 111: 507 (Aug. 6) 1938.

hyperplasia of the arterioles with but little hyalinization. Many tubules of the right kidney were greatly hypertrophied; others were obstructed. The glomeruli were enlarged; in some the basement membrane was diffusely thickened; in others there were focal hyalinization, numerous adhesions, lipid degeneration and rarely acute hemorrhagic inflammation. The alterations of the arteries were essentially the same as described for the left kidney. The veins of the kidneys were normal.

A case was reported by Freeman and Hartley³ of a man aged 57 with hypertension, presumably on the basis of arteriosclerosis of one main renal artery. Two years before death the patient had his right kidney removed following rupture caused by a fall. Histologically it was normal. In the succeeding sixteen months he was well and several blood pressure readings were normal. Eight months before death, however, his blood pressure was found to be 230/140. At postmortem examination the left kidney weighed 200 Gm. Narrowing the orifice of the left renal artery was a large arteriosclerotic plaque; no narrowing of the renal arterioles was seen. The great majority of the glomeruli were normal; some in scarred areas of the parenchyma appeared to have been recently hyalinized. In the interstitial

Fig. 1.—Hyalinization of glomeruli, pericapsular fibrosis, atrophy of tubules, interstitial fibrosis and leukocytic infiltration (hematoxylin-eosin stain; $\times 110$).

tissue was a moderate polymorphonuclear and mononuclear leukocytic reaction. A few of the tubules contained polymorphonuclear leukocytes.

Leadbetter and Burklund⁴ recorded the case of a Negro boy with an ectopic right kidney accompanied by hypertension. With its removal the blood pressure returned to normal. Apparently the cause of the hypertension was a mass of smooth muscle in the lumen of the right renal artery, markedly narrowing its lumen. No evidence of inflammatory or proliferative changes was found in the excised kidney, which was, however, of only half the normal weight.

In reviewing cases of hypertension, Oppenheimer, Klemperer and Moschkowitz⁵ found eighteen cases of unilateral narrowing of the renal artery, fifteen of which presented hypertension. There were arteriosclerosis and arteriolar sclerosis of the kidney in every case. These workers think that the intrarenal arterial changes preceded and perhaps accounted for the arteriosclerosis of the main renal arteries.

REPORT OF CASE

The case reported here is one in which the essential lesion appeared to be sclerosis of the renal arteries.

History.—A Jewish deliveryman aged 37, married, had three years before admission passed an examination for life insurance; at that time his blood pressure and urine were normal. Two years later he complained of weakness and a dull headache; he had lost 10 pounds (4.5 Kg.). A month later his systolic blood pressure was 230. He was given, without relief, weekly intravenous injections of an unknown drug by his physician. Moderately severe dyspnea began within a month, and he had edema of the ankles in the afternoon and nocturia (from one to three times). He was told that his heart was "bad" and that he had anemia. During the month before he entered the hospital the weakness increased; he was drowsy and suffered from anorexia, nausea and infrequent vomiting. There was dyspnea after climbing six steps; he also had slight orthopnea and occasional twitchings of the muscles of the arms. He had had gonorrhea in his youth and lobar pneumonia eleven years before admission. An undescended left testicle was removed when he was 16 years old. His mother has hypertension.

Examination.—He was well developed, well nourished and slightly dyspneic. The breath was uremic. There were occasional twitchings of the muscles of the hands, feet and lips. The nasal margins of the optic fundi were blurred; the arteries were narrowed and arteriovenous notching was minimal. There was no hemorrhage or exudate. The heart was enlarged, the left border being 1 cm. beyond the left midclavicular line. The second aortic sound was moderately accentuated and louder than the second pulmonic. The liver edge was felt at the costal margin.

Laboratory Data.—Hemoglobin was 35 per cent; red blood cells numbered 1,700,000; white blood cells 9,600; polymorphonuclears 79 per cent; lymphocytes 14 per cent; monocytes 6 per cent; eosinophils 1 per cent. The erythrocyte sedimentation rate was 162 mm.; serum protein 7.5 per cent; albumin 4.0 per cent; globulin 3.4 per cent; nonprotein nitrogen 262 mg. per hundred cubic centimeters, and carbon dioxide capacity 25 volumes per cent. The urine was pale and clear with specific gravity 1.010, reaction acid, albumin + + +, dextrose 0, casts 0, red blood cells 0, white blood cells occasional clumps. The Wassermann and Kline reactions were + + + +. An electrocardiogram showed some slurring of the ventricular complexes in all leads suggesting some fibrosis of the heart muscle.

The blood pressure varied from 195/120 on admission to 170/110–150/100. On the day of death it had risen to 200/120. He vomited frequently. Thirty-six hours after entering the hospital he had severe precordial pain; this was associated with a leathery friction rub over the heart. The venous pressure rose from 150 to 300 mm. of water. The total daily fluid intake was approximately from three to six times the urinary output. The nonprotein nitrogen decreased to 187 mg. per hundred cubic centimeters. The veins of his neck became more distended. During the last two days he was stuporous and had Cheyne-Stokes respiration. On the day of death the total urinary output was 350 cc. He had violent semiconvulsive twitching, which was controlled with difficulty by magnesium sulfate intravenously and by morphine. Death occurred on the sixth hospital day. The clinical diagnosis was chronic glomerulonephritis.

Necropsy.—Only the essential lesions will be discussed. There was moderate edema of the lower extremities and sacral region. The pericardial sac contained 125 cc. of clear amber colored fluid. The parietal and visceral pericardial surfaces were covered with fibrin. The heart weighed 540 Gm. The myocardium was hypertrophied; the valves and endocardium were normal.

In the ascending and transverse portions of the arch of the aorta were numerous elevated yellow intimal plaques. A few similar plaques were present in the thoracic aorta. In the abdominal aorta, in addition to a few small yellow intimal plaques, were two large areas of intimal thickening that completely surrounded and encroached on the orifices of the renal arteries and markedly reduced the size of the openings. The intimal thickening was continued for a short distance into each

nal artery. As a result of these intimal changes the orifice of the left renal artery had been reduced to a minute opening approximately 1 mm. in greatest diameter; the orifice of the right renal artery was somewhat larger, being 3 by 1 mm. in greatest diameter.

The left kidney weighed 75 Gm.; its capsule stripped with slight difficulty. A few small depressions were found on the otherwise smooth grayish yellow surface. Here and there were groups of dilated venules. The cortex varied from 6 to 8 mm. in width. The striations were not clearly defined though they did not appear irregular. The pyramids were paler than the cortex. The papillae were somewhat flattened, the calices were slightly increased in size. The pelvis and ureter were found to be normal.

The right kidney weighed 90 Gm. The capsule stripped with some difficulty. The anterior surface of this kidney resembled that of the left. The posterior surface was more irregular. At either pole and along the lateral margin it was depressed and somewhat uneven in contrast to the central elevated smooth portion. The depressed parts were grayish red and the bulging portion was yellowish gray. The cortex in the depressed areas measured 5 mm. in width and in the central elevated part 11 mm. The striations were nowhere very distinct, though not irregular. The glomeruli were vaguely seen as tiny gray dots. The pyramids were clearly defined; the papillae were somewhat flattened. The calices were slightly dilated. The pelvis and ureter were normal. The arcuate arteries in each kidney were delicate. There were a few intimal plaques in each renal artery beyond the orifice. A small aberrant artery extended into the elevated smooth portion of the right kidney.

Microscopic Examination: Since the main lesions were in the renal arteries and kidneys, the microscopic studies of these will be given in detail.

Sections of the kidneys and renal arteries were studied with a variety of stains—hematoxylin-eosin, azan carmine, elastic tissue-van Gieson and scarlet red. The intima of the renal arteries close to their orifices was thickened by a wide layer of loose meshed connective tissue whose cells were arranged parallel to the media. A few very delicate elastic fibers were found among the connective tissue cells. In the deepest part of this thickened intima of the left artery was a collection of compressed mononuclear cells and a small amount of lipid. Each intimal elastic lamella was swollen and fragmented. The media of each artery was thinner than normal; the adventitia was unaltered. The lumens of the branches of the renal arteries close to the pelvis and within the kidneys were moderately narrowed. The intima of these branches was thickened by loosely arranged fibrous tissue. Lipid was found in many of the connective tissue cells. The internal elastica was reduplicated. The media and adventitia were normal. The arterioles were not thickened, though an occasional one in the scarred areas had some lipid in its wall. No evidence of syphilitic infection was found in any of the arteries.

In both kidneys, over wide areas, glomeruli lay close together. Many of these glomeruli had thickened capsules of Bowman; in others, one or more of the capillary loops were adherent to the capsule. In many the tuft and capsule were fused together and reduced to a bloodless mass of fibrous tissue. Lipid in fine droplets was found in many of these altered glomeruli. Only rarely could tubules be identified between these damaged glomeruli. The epithelial cells of these tubules were filled with finely divided lipid. The condensed stroma in these portions of the kidneys was infiltrated with lymphocytes, and dense collections of similar cells were found at the junction of the cortex and the pyramids (fig. 1).

In the better preserved portions of the kidneys the glomeruli were somewhat larger than normal, their capillaries contained blood and the basement membrane was not thickened. The nearby tubules were moderately dilated; their epithelial cells were flat and atypical. Masses of homogeneous material resembling hemoglobin filled the lumens of many of these tubules. There was edema of the interstitial tissue but no cellular infiltration (fig. 2).

In the pyramids, some of the collecting tubules appeared normal, while others were so shrunken that no lumen could be discerned. Undoubtedly many of the collecting tubules had disappeared, as there were scattered areas in which none could be found. The epithelium of the pelvis was normal.

The central arterioles of the malpighian bodies of the spleen were sclerotic; their walls were thickened and hyalinized. The arterioles of other viscera were normal.

The anatomic diagnosis was atherosclerosis of the aorta, stenosis of the orifices of the renal arteries, atrophy of the kidneys, cardiac hypertrophy and dilatation, acute serofibrinous pericarditis, ascites, hydrothorax and edema of the legs.

COMMENT

The case here reported was of especial interest to clinicians, particularly as regards the character of the renal lesion. Against the diagnosis of malignant hypertension were the marked albuminuria, the severe anemia and the slight arterial lesions and absence of exudate or scarring of the optic fundi. Pyelonephritis was considered an unlikely probability as there was nothing in the history to suggest a previous infection of this

Fig. 2.—Section through the better preserved portion of the right kidney. The tubules are dilated and their epithelium is flattened. The glomerulus is larger than normal. Interstitial tissue is edematous (hematoxylin-eosin stain; $\times 260$).

type. Since the kidneys could not be palpated, renal insufficiency due to congenital polycystic disease was thought to be most unlikely. There remained for consideration chronic glomerulonephritis and, though certain of the features of the case were atypical, this was the final clinical diagnosis. The appearance of the kidneys was not suggestive of typical chronic glomerulonephritis. The broad depressed areas in the renal cortex resembled those seen in healed pyelonephritis. Against this diagnosis is the absence of any evidence of dilatation of the pelvis or ureter and of any indications of a previous or recent infection of these structures. The histologic lesions in the kidneys are obviously not those of chronic glomerulonephritis or of pyelonephritis. The absence of arteriolar sclerosis eliminates the possibility of this vascular lesion being the cause of the renal damage.

There remains for discussion the sclerosis of the renal arteries. The great reduction of the size of the orifices of these arteries must have resulted in an ischemia sufficiently marked to produce renal atrophy. The gross and histologic alterations in the kidneys are such as might be expected to follow marked ischemia. Further support for this view is afforded by the fact that the least affected portion of either kidney is that part having an additional blood supply through the aberrant artery.

USE OF VITAMIN G IN PEMPHIGUS

REPORT OF A CASE OF PEMPHIGUS VULGARIS TREATED SUCCESSFULLY
WITH RIBOFLAVINMALACHI C. TOPPING, M.D., AND AUGUST F. KNOEFEL, M.D.
TERRE HAUTE, IND.

The treatment of pemphigus has always been most unsatisfactory, as testified to by the numerous therapeutic agents in use.¹ There are two main types of pemphigus: the acute type in which death occurs in a few weeks, and the chronic type in which often there is a lapse of several years before death supervenes. The most common manifestation of the chronic type is known as pemphigus vulgaris. The use of vitamin therapy in the treatment of this disease is not without precedent. In 1932 Ludy and DeValin reported the uncomplicated recovery in six patients of pemphigus under massive dosage with viosterol. King and Hamilton² have also reported a case controlled by vitamin D therapy.

Many writers remark on the incidence of the disease among the lower strata of society, wherein deficiency diseases are most frequently encountered. Ludy reported that all his patients had subsisted on an unbalanced diet deficient in vitamins. A search of the literature, however, fails to reveal any one's use of vitamin G in the treatment of pemphigus. Its use in this case was on a purely experimental basis and was not predicated on known prior work except as mentioned herein.

General physical examination was essentially negative. He was muscular, of medium height and apparently well nourished. The temperature varied between 98 and 100 F., the pulse between 90 and 110. The Nikolsky sign was present. The Kahn test gave negative results. Analysis of the blood showed hemoglobin 99 per cent (15.04 Gm.), erythrocytes 4,770,000, leukocytes 10,200, polymorphonuclears 56 per cent, lymphocytes 36 per cent, monocytes 8 per cent. The Schilling count was 0-0-6-50. Urinalysis was made on a voided specimen; it was straw colored and slightly cloudy with a specific gravity of 1.024 and an acid reaction. There was no albumin, sugar or acetone present. An occasional epithelial and an occasional pus cell were reported. Blood cultures showed no growth in forty-eight hours. Fasting blood sugar was 104 mg.

Treatment was started with sulfanilamide 0.66 Gm. and sodium bicarbonate 1.33 Gm. three times a day. Continuous wet dressings of aluminum acetate solution were used on the lesions. Neoarsphenamine 0.6 Gm. was given intravenously every fourth day. June 2, fourteen days after admission, there was no indication of any improvement. The lesions present showed no evidence of healing and new lesions continued to appear. Wet dressings were discontinued and starch water and sodium bicarbonate baths were instituted three times a day. Between baths the body and sheets of the bed were freely covered with cornstarch powder. Neoarsphenamine and sulfanilamide were continued as before. June 27, thirty-nine days

Temperature, pulse and respiratory course during hospitalization.

Our purpose in this preliminary report is not to advance or recommend its use but to report a single case in which it apparently effected a rapid and remarkable cure. The material was made by an experimental laboratory and assayed to 970 Sherman-Bourquin units per gram. It is not available for distribution, but sufficient has been made available to two dermatologic clinics for controlled use. A detailed report of their results will be published at an early date.

REPORT OF CASE

H. W., a white man aged 51, married, a coal miner, seen May 19, 1939, complained of a generalized cutaneous eruption of four months' duration covering the entire body, including the right side of the face and the scalp. He stated that the lesions appeared as blisters and that new lesions appeared every few days. He complained also of itching and severe burning pain, associated especially with any activity or sweating. Weakness and vertigo were also present. The lesions consisted of discrete bullous areas measuring from 0.5 to 4 cm. in diameter, situated on an erythematous base. The older lesions were ruptured and in places confluent. They were weeping seropurulent exudate and were covered with incrustations.

after admission, no change was noted. The starch water baths were of benefit in keeping the old infected lesions free from crusts, but otherwise there was no change in his condition. The temperature chart showed a consistent evening rise in temperature to 100 or 100.2 F., the pulse rate showing a corresponding increase.

July 7, the fiftieth day after admission, flavin concentrate 1 Gm. containing 970 Sherman-Bourquin units of vitamin G per gram was administered in orange juice and repeated daily thereafter. There was an immediate flattening of the daily temperature and pulse curves, as clearly shown in the accompanying chart. No new lesions appeared after the beginning of its administration and the old lesions, for the first time, showed definite evidence of healing. Starch baths were continued but all other medication was stopped. The patient was discharged from the hospital July 20, the sixty-third day, and has been seen at weekly intervals since. The old lesions have practically disappeared; there remain only a few erythematous and slightly pigmented areas over the back and chest. No new lesions have appeared. He makes no complaint at the present time except of weakness. His appetite is good, he sleeps well, his temperature remains normal and he has resumed all his usual activities except work in the coal mine. Resumption of this depends to some extent, perhaps, on the adjudication of his claim for workmen's compensation.

BILATERAL HABITUAL DISLOCATION OF THE
SHOULDERS IN TWINS

A FAMILIAL TENDENCY

PAUL B. MAGNUSON, M.D., AND JAMES K. STACK, M.D., CHICAGO

The medical literature of the past twenty-five years is replete with articles dealing with recurrent or habitual dislocation of the shoulder. The 250 or more procedures or modifications advocated for the correction of this condition attest the difficulties of finding the ideal one. Most authors stress methods of treatment, but occasionally a pedagogic outline of the subject is found in which etiology and pathology are discussed as well. The discussion of etiology usually revolves around (1) trauma and (2) "a congenital factor." There seems to be little question that severe trauma to the supporting structures of the shoulder will, in the event of improper care (or occasionally with proper care), result in a laxity which will predispose the shoulder to further dislocations. The "congenital factor," however, is referred to in a vague and cursory manner. A congenital elongation of the capsule or its muscular supports, congenital malformation of the humeral head or shallowness of the glenoid cavity are mentioned frequently but seldom with the authority of reports or observations in the dissecting or operating room.

Such an attitude is reasonable, however, because (1) the region of the shoulder and its contiguous structures is a difficult and hazardous field in which to carry out a complete exploration and (2) most of the operations which succeed in correcting habitual dislocation are designed to obviate this necessity by plastic procedures on a remote part of the joint. A capsular plication, any variety of tendon or fascial suspension or an anterior bone block may be done in a purely mechanical way, without first finding the lesion and then correcting it, which is the usual operative procedure. A familial tendency to this vague "congenital factor" is occasionally mentioned by other authors, but we feel that it is effectively illustrated in the instance of the following cases:

REPORT OF CASES

Ri. and Ro. K., male twins aged 19 years, white, were admitted to Passavant Memorial Hospital on Dec. 20, 1934. Each was 5 feet 5 inches (165 cm.) tall. Ri. weighed 126 pounds (57 Kg.) and Ro. 137 pounds (62 Kg.).

The relevant family history was as follows: The father, a paternal uncle and an older brother had habitual dislocations of the right shoulder. Another brother had habitual dislocations of both shoulders. Two sisters had no such difficulty but one sister "had dislocations of her knee until the age of 11." She has had none since.

Ri. stated that the first dislocation of the right shoulder occurred when he was 11 years old. It was caused by a horse stepping on his arm. No further dislocation occurred until he was 17, when the right shoulder "came out" during a football game. He was able to replace it himself, but afterward it became dislocated about once a week. The left shoulder first became involved at the age of 18 while he was playing basketball. He did not consider the injury unusual. During the following year this dislocation was repeated about eight times. He stated that the right shoulder was most easily displaced by throwing motions, while the left was displaced by blows on the arm when it was outstretched over the head.

Clinical and x-ray examination of the shoulder revealed nothing remarkable. The distance between the acromion process and the lateral condyle was the same on the two sides, as was the distance between the lateral condyle and the distal border of the palpable insertion of the pectoralis major. There was no evidence of capsular relaxation of other joints, nor had any other been dislocated.

Ro. stated that his right shoulder first became dislocated when he was 16. Since then such occurrences had been frequent. Any act in which the arm was abducted beyond the horizontal level could precipitate a dislocation. He could replace

it without aid. He first dislocated the left shoulder at the age of 17 and since then had dislocated this shoulder six or seven times. On each occasion it was necessary for him to have an anesthetic before reduction could be accomplished. Here, as in the case of his brother, no clinical or x-ray changes of note could be found. In neither case was the primary trauma unduly severe.

December 21, one shoulder of each boy was operated on, a Nicola teno suspension being done. On March 10, 1935, the same procedure was carried out on the other shoulder of each patient. Two years after the second operation one shoulder of one boy again became dislocated following severe violence in the abducted and extended position. Exploration of the shoulder was carried out and no cause could be found. No recurrence has been reported since.

TYPHOID IN THE LARGE CITIES
OF THE UNITED STATES
IN 1939

TWENTY-EIGHTH ANNUAL REPORT

As in past years, the information used in the compilation of this report was secured by addressing a communication to the health officer of each of the ninety-three cities, requesting the number of deaths from typhoid both among residents and among non-residents which were recorded in 1939. As the population figures of the 1940 census are not yet available, the uncertainty of rates based on local estimates is recognized. In all instances the local estimate when furnished by the health officer has been used. With

These patients were referred by Dr. R. W. Doud of Normal, Ill. From the Division of Surgery, Northwestern University Medical School.

Read before the Chicago Surgical Society, Dec. 6, 1939, and before the American College of Surgeons, sectional meeting, New Orleans, Jan. 19, 1940.

statistical error has been committed by using the local estimate rather than falling back on the 1930 census figures. In fact, any such error is insignificant when compared with the variety of figures on typhoid deaths which are submitted (through different channels) by the same local health department or the state health

* All typhoid deaths were stated to be in nonresidents.

† One third or more of the reported typhoid deaths were stated to be in nonresidents.

Incomplete data.

† Typhoid deaths furnished by Pennsylvania Department of Health, Harrisburg.

department. All reallocations by place of usual residence or by source of infection are not completed at the time this report is prepared. There are some cities and states in which reallocations are apparently never prepared. There is great need of uniformity in this respect. It is expected that after the 1940 census figures become available this report can be revised, but even then it is anticipated that the corrections will be of only a minor character.

Paratyphoid has again been excluded. In tables 1 to 8 inclusive (as well as in table 10) a special note has been made of cities in which all deaths occur among nonresidents. This practice was applied first to the figures for 1937 and has been continued through 1939. Another symbol has been used to indicate those cities

TABLE 3.—*Death Rates of Nine Cities in South Atlantic States from Typhoid per Hundred Thousand of Population*

Incomplete data.

in which more than one third of the reported deaths were stated to have been among nonresidents.

Special attention is called to the cities listed in table 9 which report no typhoid death during the past two or more years. Bridgeport heads the list with no death in six years. Fort Wayne reports no death in five years, South Bend and Utica no death in four years, Fall River, Lynn, Milwaukee, New Bedford and Wichita no death in three years. Attention is also directed to

the ten cities (Fort Worth, Scranton, Louisville, Norfolk, Canton, San Diego, Dallas, San Antonio, Camden, El Paso) which were not placed on the honor roll in table 10 merely because they have been charged with deaths among nonresidents. These cities may appropriately be considered as belonging in the honor group. Some cities are far more liberal than others in their attitude in accepting for hospitalization cases of communicable disease from the neighboring rural areas. In some instances legal circumstances compel the city to accept cases from the county.

Eleven of the large New England cities (there were only seven in 1938) report no death from typhoid in 1939 (table 1). Bridgeport has extended its good record to six years. Fall River, Lynn and New Bedford record no death in three years; Cambridge and Lowell,

none in two years. Somerville, after passing through four successive years without a death, followed by one death among residents in 1938, now returns to the honor roll with no death in 1939. Springfield reports no death among residents during the past five years, Worcester none for four years, Hartford none for two years. Of three deaths reported from Boston, two occurred in nonresidents. There were only three deaths among residents in the fourteen cities in the New England states (one each in Boston, Providence, New Haven)—a truly remarkable record. The New England cities as a whole (population 2,657,824) have regained first place among the grouped cities (table 13). This enviable place was lost in 1938 to the cities of the East North Central states, which now find themselves in third place in 1939. The Middle Atlantic cities are in second place. In the New England cities there were

recorded six deaths in 1939, only one half the number for 1938 and 1937.

The Middle Atlantic states (table 2) have a group rate (0.37) which is lower than that of 1938 (0.44) and 1937 (0.51). There has been no death recorded in Utica for the past four years, none in Elizabeth for two years. Eight cities (Utica, Elizabeth, Syracuse, Paterson, Yonkers, Jersey City, Albany, Trenton) report no typhoid death in 1939. There were six such cities in 1938, seven in 1937. Scranton records no death among residents during the past six years, Camden none for two years. Buffalo, after two years with no death among residents, reports one such death in 1939; Erie, after no death among residents in four years, reports two such deaths in 1939. Newark records the highest incidence of typhoid in twelve years (twenty-five cases) and the largest number of deaths in seven

years (seven deaths). It is stated that practically all of the cases were due to contact with a mild case acting as a carrier. New York reports twenty-two deaths (the same number as in 1938), of which twenty (as in 1938) were among residents. Philadelphia reports twelve deaths (fifteen in 1938), six among residents. Pittsburgh reports three deaths, two among nonresidents. After two years with no death, Reading reports one death among residents. The health officer of Scranton records no typhoid death; however, the Pennsylvania Department of Health has charged one death to this city. Syracuse reports no death among residents during the past four years. In the group as a whole (population 13,602,500) there were fifty-one deaths in 1939 compared with fifty-nine in the preceding year. There was but one geographic area which had a lower death rate for 1939, the New England.

The rate (table 3) for the South Atlantic cities (1.03) is much improved over the rates of 1938 (1.74) and 1937 (1.96) and is considerably lower than that of 1936 (1.55). It is but slightly more than a third

the rate for the quinquennial period 1931-1935 (2.70). In these cities (population 2,622,237) there occurred twenty-seven deaths in 1939 and forty-six in 1938. There was but one city (Wilmington) without a death in 1938, although Norfolk recorded its one death among nonresidents. Nine (one third) of the deaths

TABLE 8.—Death Rates of Eleven Cities in Mountain and Pacific States from Typhoid per Hundred Thousand of Population

* All typhoid deaths were stated to be in nonresidents.

† One third or more of the reported typhoid deaths were stated to be in nonresidents.

Incomplete data.

in the group of cities as a whole occurred among nonresidents. The percentage of deaths among nonresidents is less significant than for former years. Of seven deaths recorded for Atlanta, two were among nonresidents; of four in Washington, one was among nonresidents. Baltimore records but one death among residents (five among nonresidents). The health officer states that only twenty-four cases (less than half of any previous year) were reported in Baltimore. The three deaths in Richmond, three in Jacksonville, two in Miami and one in Tampa occurred in residents.

The East North Central cities (population 9,883,376) experienced a setback and dropped from first place in 1938 to third in 1939 (table 4). The number of typhoid deaths increased from thirty-five to forty-four (the rate from 0.35 to 0.44). The rate remains, however, below that of 1937 (0.62) and of the quinquennial period 1931-1935 (0.75). As in 1938 there are seven cities (Fort Wayne, South Bend, Milwaukee, Akron, Evansville, Flint, Dayton) which report no death in 1939. They are not, however, altogether the same cities. Grand Rapids with one death among residents in 1939, Canton with one among nonresidents, Youngstown and Peoria each with two deaths among residents, have been

TABLE 9.—Fourteen Cities with No Typhoid Death in 1938 and 1939

‡ No typhoid death in three years.

dropped from the honor list. There are four cities (Cleveland, Columbus, Cincinnati, Indianapolis) in which one third or more of the reported deaths were stated to be among nonresidents. Fort Wayne reports no typhoid death in five years, South Bend no death in four years, Milwaukee no death in three years. Chicago reports nine deaths, all among residents. Of five deaths each in Cincinnati and Cleveland, two were among nonresidents. Of eight deaths in Detroit, one was among nonresidents. The health officer reports that, of twenty-

six cases, nine obtained their infection while out of the city, five were infected by contact with typhoid carriers, one was reallocated to Detroit from a neighboring township, and in eleven instances the source of infection could not be ascertained.

1939.....	93	0	3	7	17	32	34

and that of the quinquennial period 1931-1935 (4.81). The actual number of deaths in these six cities increased but one, from thirty-two in 1938 to thirty-three in 1939. For the first time, one of these cities (Chattanooga) is included in the list of those cities without a death in 1939. In addition to these there are three cities (Birmingham, Nashville, Memphis) in which one third or more of the reported deaths were stated to be among nonresidents. It is here evident that the surrounding

rural areas continue to contribute to the hospital load and thus to the death rate of these urban centers. Birmingham, with three deaths, reports one among nonresidents; Nashville, with five deaths, records four in nonresidents; Memphis, with seventeen deaths, reports twelve in nonresidents. The health officer of Memphis reports twenty-eight cases in residents: six among white persons, twenty-two among Negroes. The attack rate for Negroes is nearly six times that of the white population. Since Memphis serves as a hospital center for the surrounding territory, thirty-six additional cases were brought into the city for treatment (thirteen white with five deaths, twenty-three Negroes with seven

TABLE 12.—*Total Typhoid Rate for Seventy-Eight Cities 1910-1939**

* The following fifteen cities are omitted from this table because data for the full period are not available: Canton, Chattanooga, Dallas, Fort Wayne, Jacksonville, Knoxville, Long Beach, Miami, Oklahoma City, South Bend, Tampa, Tulsa, Utica, Wichita, Wilmington.

† Data for Fort Worth lacking.

‡ The rate for ninety-three cities in 1935 was 1.03 (total population 37,437,812, typhoid deaths 385), whereas in 1930 it was 1.61 and in 1923 and 1934 it was 1.24 and 1.25 respectively. The 1931-1935 average for the ninety-three cities is 1.31.

§ Rate for ninety-three cities in 1936 was 0.96 (total population 38,249,094, typhoid deaths 365).

Rate for ninety-three cities in 1937 was 0.92 (total population 38,885,435, typhoid deaths 318).

Rate for ninety-three cities in 1938 was 0.74 (total population 39,143,556, typhoid deaths 291).

Rate for ninety-three cities in 1939 was 0.67 (total population 39,354,549, typhoid deaths 265).

Special Note:—Deaths for 1936 have been corrected, as Yonkers originally reported seven deaths and later corrected report to one death.

deaths). As one third of the nonresident patients died, it is fair to conclude that only the unfavorable cases were hospitalized, the milder cases not being sent to Memphis. Knoxville records five deaths, four among residents. Louisville deserves special mention as all three deaths were among nonresidents.

The West North Central group (table 6) (population 2,809,679) shows an increase in the death rate (0.50 in 1939, 0.40 in 1938). In second place in 1938, this group in 1939 just edges out the Mountain and Pacific group for fourth place. The increase in the number of deaths is but three (from eleven in 1938 to fourteen in 1939). As in 1938 there are four cities (Wichita, Kansas City, Kan., St. Paul, Duluth) which report no death in 1939. They are not, however, altogether the same cities. Minneapolis and Omaha, each with one death among residents, have been dropped from the honor list. Minneapolis had reported no death

among residents for three years prior to 1939. Duluth returns to the honor roll after an absence of one year (no deaths in 1936 and 1937). Only one death has occurred in Duluth during the past four years. In 1938 this was the only group in which there was no city with a death rate in excess of 1.0. In 1939 there is no such group, although the West North Central cities maintain second place (Des Moines with 1.3) while the

TABLE 13.—Total Typhoid Death Rate per Hundred Thousand of Population for Ninety-Three Cities According to Geographic Divisions

† Data for South Bend for 1925-1929 are not available.

‡ Lacks data for Oklahoma City in 1926.

New England cities take first place (New Haven with 1.2). Kansas City, Kan., reports no death among residents for the past three years, while Wichita records no death either among residents or nonresidents for three years. Of six deaths in St. Louis and four in Kansas City, Mo., three each were among residents.

The eight cities of the West South Central group (table 7) (population 2,138,496) report a reduction in the death rate (3.52 in 1938, 3.19 in 1939). The actual number of deaths decreased from seventy-four to sixty-eight. Special mention should be made of El Paso and San Antonio, each reporting six deaths, all among nonresidents; Dallas recording five deaths and Fort Worth one death, all among nonresidents. New Orleans reports thirty-six deaths, twenty-four among nonresidents. Excluding New Orleans, there were thirty-two deaths reported by the cities in this group, of which twenty-one, or two thirds, were among nonresidents. Houston reports six deaths, three among residents; Oklahoma City six, all among residents.

The cities in the Mountain and Pacific states (table 8) report the same number of deaths as in 1938 (twenty-two) and consequently but a slight reduction in the rate (0.51 in 1939, 0.52 in 1938). While in 1938 there were five cities with no death, in 1939 there were but two (Salt Lake City, San Francisco) such cities and only Salt Lake City appears on the honor roll for the two years. San Diego with no death in 1938 and two deaths among nonresidents in 1939 deserves special mention. Tacoma, Portland and Seattle, each with one resident death, have been dropped from the honor roll. Spokane records three deaths, two among residents. Denver reports six deaths among residents and does not keep a record of deaths among nonresidents. Los Angeles records six deaths, five among residents. In October 1939 thirty-five cases in the city and ten additional cases in the county were caused by a carrier who contaminated chocolate éclairs.

THE HONOR ROLL

The number of cities with no death from typhoid has increased to thirty-four. In 1936 there were but eighteen such cities, in 1937 twenty-seven, in 1938 twenty-nine. Of particular significance are the data in table 9, which furnishes the names of fourteen cities

with no typhoid death in 1938 and 1939. Several cities have continued their excellent records. We again find (as in 1938) three cities in the third rank (table 10). It should be emphasized, however, that in El Paso all deaths were stated to be in nonresidents and in Memphis twelve of seventeen deaths were in nonresidents. As repeatedly stated, several other cities in the first and second rank would appear in the honor roll were they not charged with deaths in nonresidents. Table 11 continues to show a definite swing "to the right" with a marked reduction in the number of cities with a rate of 2.0 and above.

For the seventy-eight cities (table 12) for which data are available since 1910, there occurred 239 deaths from typhoid in 1938, which is the lowest of record (248 in 1938, 280 in 1937). The rate for this group of cities is for the fifth consecutive year less than 1.0. The rate for the ninety-three cities studied in 1939 is also below 1.0 (0.67) and below the corresponding rate for 1937 (0.74). This annual review again shows a downward trend in the death rate from typhoid in the large cities of the United States. No outbreak of epidemic proportion has been recorded in these cities. Routine vaccination of the population is not practiced except under flood conditions. In progressive communities vaccination is urged for contacts to cases and for persons who travel widely in countries where sanitary conditions are not of the best. Noteworthy gains have been made throughout the country. The New England and Middle Atlantic groups have maintained their excellent rates of many years' standing.

OVARIAN HORMONES AND FEMALE GENITAL CANCER

EDGAR ALLEN, PH.D.

Professor of Anatomy, Yale University School of Medicine
NEW HAVEN, CONN.

This paper does not attempt to summarize even the most recent work in this field. Instead, it merely outlines the development of my own point of view on the subject from the early work on the follicular hormone in which normal reactions were reproduced to work of more recent date indicating a possible role of this hormone in mammary and uterine cancer. Since the early work with Dr. Doisy on this hormone was done in St. Louis at Washington University School of Medicine, it means a great deal to me now¹ to be able to present some more recent studies which have led to the experimental production of genital cancer.

I intend first to summarize briefly some of the principal results obtained in studies of animal reactions to ovarian hormones, especially estrogenic hormone, emphasizing above all its effect of producing growth in the female genital organs, for it seems to me that estrogenic hormone above all else is a growth hormone, concentrating its action on the female genital organs.

In the normal animal, after this genital growth hormone has been acting for a while, the genital tissues are raised to a high plane of function, which is usually rather transitory. Then there is a phase of retrogression, especially in the vagina and uterus and to some

The first Barnard Hospital Lecture, read before the St. Louis Medical Society, Oct. 31, 1939.

1. It is a special honor to be invited to give this first Barnard Hospital Lecture, inaugurated under Dr. E. V. Cowdry's directorship of research in this hospital. Contacts with him and with three of his predecessors, Dr. Leo Loeb, Dr. Montrose T. Burrows and Dr. George M. Smith, have contributed a great deal to the development of the point of view expressed herein.

extent also in the mammary glands. In some animals a period of rest intervenes before the estrogenic hormone again reaches a concentration high enough to start another phase of growth in the genital organs.

After summarizing some of the effects of estrogens in experimental animals when the hormone is given in small doses over short periods, attention will be focused on what can be done by long continued treatment with this growth producing hormone in high doses.² In other words, instead of permitting the genital organs to regress and rest briefly after short phases of growth and function, the experiments attempt to keep them growing more or less continuously over long periods. Under such conditions it is possible to produce quite abnormal growths—decidedly atypical growths—and in some cases cancer follows.³

Of course, there may be many etiologic factors in cancer other than hormonal stimulation: genetic, traumatic, chemical, parasitic, and even bacteria, viruses and other factors. Obviously hormonal stimulation is only one of several factors in the etiology of female genital cancer.

A BEGINNING

Because this paper is to sketch my own point of view on this subject, I wish to mention briefly the background. After two years in the army, with graduate work toward a Ph.D. degree incomplete, and never having been farther west than Buffalo, I came to St. Louis in the fall of 1919. My start was as instructor in anatomy in Dr. Terry's department at Washington University School of Medicine. As training for this job of teaching and investigation in a medical school I had had only preparation in zoology.

It was necessary for me to get started on a doctor's thesis. I had been most interested in embryology—in reproduction. No one had succeeded in attempts to fertilize mammalian eggs in vitro. This still seems to me a most interesting problem.

Dr. Charles H. Danforth, now professor of anatomy at Stanford University School of Medicine, had a colony of mice on which he was studying the inheritance of such characteristics as a hereditary anemia present before birth, hereditary obesity peculiar to yellow mice, and other things. This was my introduction to inbred strains of mice as experimental animals *par excellence*.

Seven months of attempting to fertilize mouse eggs yielded only failure. In attempts to get the eggs it was necessary to learn something about the nonpregnant sexual cycle. When the first objective (fertilization in vitro) failed, the estrous cycle became the subject of my thesis, and this led directly to my early work with Dr. Doisy and others on the ovarian follicular hormone.

The problem considered in the thesis was strictly morphologic. The ovary and genital tract were studied microscopically and an attempt was made to explain function by correlating the results.⁴ It was observational. There was no experimental work involved. At that time most statements concerning the internal secretions of the ovaries stressed the corpora lutea as the endocrine glands of the ovary. Clinical books especially, with their emphasis on implantation, seldom mentioned the follicles as possible endocrine structures. Leo

Loeb⁵ and Stockard and Papanicolaou,⁶ working with the guinea pig, and Long and Evans,⁷ working with the rat, had recognized the importance of the follicles in hormone secretion, but their work, like mine with the mouse, was mostly observational and did not include experimental tests of ovarian extracts.

The point that impressed me most strongly from the work on the mouse was that there might be a succession of nonpregnant cycles without ovulation and consequently without the formation of corpora lutea; in other words, that the follicular hormone alone should be sufficient to explain the succession of cyclic phenomena in the nonpregnant uterus and vagina. This focused my attention on the liquor folliculi as a source of this hormone.

At that time the discovery by Banting and Best of insulin had just made investigators hormone conscious, and Drs. Shaffer and Doisy were working intensively on insulin. Dr. Doisy undertook the chemical fractionation of follicular fluid. It is fun now to recall picking over ovaries from a bucket in the meat packing plant, my wife and I aspirating the fluid from the follicles on the kitchen table at home, Dr. Doisy beginning his extraction of the active fraction and our early tests of follicular hormone on mice. One of the remarkable things about that first experiment was that all the animals injected gave positive reactions.⁸

Growth in Female Genital Organs Produced by Estrogens.—Even in those first experiments it was clear that the outstanding effect of this hormone was to produce growth in the female genital organs. This was clearly shown by the vaginal reaction, in which growth in forty-eight hours thickens the vaginal wall of the castrate rodent from two or three layers to more than a dozen layers.⁹ In most instances the treatment was of short duration and the dosages were very small. In the first years of work with this hormone, concentrated extracts were not available. Later crystallization¹⁰ and then synthesis¹¹ of estrogens was accomplished. More than forty substances are now available for which estrogenic activity has been demonstrated.

Estrous Cycles, Successive Waves of Growth.—One of the points which seemed to me most important in the reaction of rodents to injected estrogen was that experimental estrous cycles could be produced by the injection of this follicular hormone. This must mean that, fundamentally, the normal nonpregnant cycle in the vagina and uterus of the mouse was merely a succession of waves of growth, at the peak of which would occur short periods of function and which would be followed by periods of retrogression. In fact, in the normal mouse and rat there is no luteal phase of the cycle unless the animal is mated. It requires cervical stimulation to activate the corpora lutea. So, as far as the nonpregnant cycle in these animals is concerned,

the corpora lutea are not important. It should be noted that this refers to the nonpregnant cycle. When this statement was made in a paper presented at the Washington University Medical Society, the comment by a prominent clinician was that, while this might be true in the mouse and rat, it certainly didn't apply to the menstrual cycle in women.

Experimental Menstrual Cycles.—This comment led to attempts to produce experimentally menstrual cycles in monkeys. The first work was begun here during the summer of 1923. Later it was possible to establish a colony of monkeys at the University of Missouri and repeat on monkeys this work begun on rodents. The first menstrual cycles experimentally induced by injections of ovarian hormone were completed in castrate monkeys¹² in 1927. It was six years later (1933) that Werner and Collier¹³ at St. Louis University School of Medicine produced the first experimental menstruation in ovariectomized women with theelin. Six years was a long time to wait for confirmation in women of experimental menstruation. At that time the accepted explanation of function of the corpus luteum was preceded by cessation of menstruation was preceded by observations on normal animals in which menstrual cycles without ovulation were demonstrated, indicating that the corpus luteum was not essential to menstrual function.

Much opposition immediately arose from clinical sources to the radical idea that the follicular hormone alone was sufficient to explain the fundamental mechanism of menstruation. Some gynecologists still call menstruation without ovulation a pseudomenstruation, although it is difficult or impossible to distinguish it externally from menstruation following ovulation. It is true, of course, that the corpus luteum hormone, progesterone, is necessary to transform the endometrium into its progestational condition (Corner and Willard Allen,¹⁴ Hisaw and his collaborators¹⁵). Also progesterone will hold off or postpone the menstruation which follows withdrawal of estrogen, as shown by Smith and Engle¹⁶ and by Hisaw.¹⁷ But so will continued injections of estrogen. The endometrium can be kept growing for months without menstruation in castrate monkeys if the dose of estrogen is raised and maintained.¹⁸ Also the male hormones testosterone and androsterone will postpone menstruation after withdrawal of estrogen.

Again in the experiments with estrogens in adult monkeys,¹² although menstruation was the most obvious external character, the principal point emphasized was the growth induced by the hormone in the female genital organs.²

Accelerated Prepubertal Growth.—It is also possible by injecting small amounts of estrogen to induce the prepubertal growth of the genital organs in both rodents¹⁹ and primates.²⁰ This was done experimentally with estrogen before the gonadotropic function of the pituitary was discovered, with the work of Smith and Engle,²¹ Zondek and Aschheim,²² Hisaw²³ and others on the anterior pituitary gonadotropic hormone; that is, the latter segment of the endocrine chain, the ovarian-genital tract reaction, was worked out and ready for association with the anterior pituitary ovarian reactions.

Mammary Growth.—In the monkey the mammary glands react to estrogen alone by growth of both ducts and alveoli.¹² In some animals it apparently requires the additional action of progesterone for full growth of the alveoli, just as it does for production of a progestational endometrium.

EARLY ATTEMPT AT CERVICAL CANCER

The beginning of my point of view on experimental cancer was an appreciation of the estrogenic hormone as a stimulator of growth of female genital tissues and the vague recognition that a definition of cancer must include the matter of growth—excessive and atypical growth. At a meeting at which the early recognition of cervical cancer was the subject, lantern slides were shown of precancerous conditions of the uterine cervix. A condition of leukoplakia was described and the development of many epithelial pegs along the base of a hypertrophied epithelium was emphasized. These sections were quite suggestive of results obtained in the cervix of the monkey by estrogenic stimulation. They raised the question "Why not try excessive estrogenic stimulation for a long period of time to see if further abnormal growths might be produced?" With Dr. Overholser a series of experiments was begun which consisted of daily injections of estrogens for several months. Some of the experiments were carried beyond a year. Abnormal growths including metaplasia of the cervical glands and marked epithelial overgrowth were induced²⁴ and were diagnosed histologically by others as precancerous.

Lacassagne's Work.—At this time (1932) Lacassagne²⁵ published his successful experiments which recorded the occurrence of mammary cancer in male mice which had been feminized by injections of estrogenic hormones. Estrogen stimulated growth in the mammary rudiments of the male until they were equivalent to the mammary glands of adult females, and then a considerable percentage of the males died of mammary cancer.

Work at Yale.—Complete confirmation of this work of Lacassagne's has been possible at Yale. In the early stages of work at Yale (1933) it became possible to

affiliate Dr. L. C. Strong, a geneticist and former associate of C. C. Little, with the Department of Anatomy. Dr. Strong brought with him a colony of inbred cancer mice which seem to have many types of cancer known in human beings. We also obtained the collaboration of Dr. William U. Gardner, who had studied at the University of Missouri with Dr. Turner the responses of the mammary tissue to estrogen and other hormones. Then Dr. G. M. Smith, surgeon and pathologist, who was formerly a member of Dr. Opie's department at Washington University in prewar days and a former director of research at Barnard Hospital, collaborated as pathologist. Without his point of view as pathologist, those of us without clinical training might well have hesitated in embarking on investigations of cancer. Then Drs. William Greulich, Carroll Pfeiffer and Warren Nelson were added to our group²⁶ and an intensive attempt to produce cancer by excessive estrogenic stimulation was begun.²⁷

Inbred Strains of Cancer Mice.—By inbreeding, involving brother to sister mating, more than a dozen different genetic strains of mice have been established with varying susceptibility and resistance to cancer.²⁸ Some of these are as different in characteristics and reactions as are Negroes and white persons. While mammary cancer has been studied most intensively, there are other types of cancer represented in these inbred mice.

In one strain of inbred mice, mammary cancer appears spontaneously in more than 80 per cent of all females before the age of 12 months. It requires only a few weeks for a small palpable nodule to become a large mammary cancer and not very much longer before the mouse dies of this cancer. The inheritance of this disease has been followed through more than forty generations, and in each generation one or more of the females have died of mammary carcinoma.

Sexual Cycles in Cancer Mice.—A challenging question was "What happens to the reproductive system when mammary cancer begins to grow rapidly and to produce a serious drain on the body?" It was known that estrogenic hormones stimulate growth of the mammary glands. Does rapid growth of mammary tissue in a cancer upset the endocrine balance necessary for rhythmic estrous functions in uterus and vagina, which also require estrogenic hormone? Estrous cycles were recorded in cancer mice as soon as the tumors became palpable. As the tumors grew rapidly, the estrous cycles lengthened, became irregular and in some cases disappeared altogether. Microscopic sections showed the vagina and uterus to be very atrophic, similar to the condition of castrate animals, and the ovaries to be very small, like those of very old mice. These animals were by no means old enough to have reached the natural menopause (if one may use that term for a mouse).

Injections of estrogens into these cancer mice induced full estrous growth in both vagina and uterus and secretion in the uterus.²⁹ Estrogenic treatment did not seem to affect the growth of the cancerous nodules. Implants

of anterior pituitary tissue stimulated the ovaries to follicular growth with, secondarily, estrous conditions in the vagina and uterus. Therefore, both genital tract and gonads in these cancer mice were still reactive. The premature senility of the genital tract was apparently due to inadequate supply of ovarian and anterior pituitary hormones.

Survey of Mammary Glands in Ten Strains of Mice Varying in Susceptibility to Cancer.—While attempting to repeat Lacassagne's observations, a thorough search was made for differences in the mammary glands of ten strains of mice—some cancer susceptible and others cancer resistant.³⁰ Whole mounts of all the mammary tissue in these animals at representative stages of life were studied and foundations of normal conditions laid for later studies of mammary cancer. Many interesting things have been found such as (1) failure of development of the third pair of nipples in one particular strain of mice, (2) failure of some mammary gland rudiments of the male to respond to estrogens while others in the same mouse did respond and (3) persistence of hyperplastic nodules in involuting mammary glands of old mice which seem peculiar to animals of cancer susceptible strains. The existence of multiple hyperplastic nodules at this age provides several potential loci for cancer, and when one grows rapidly into a cancer and is removed another may accelerate growth and become lethal. This is not due to metastases but to multiple hyperplastic loci, with potentialities for development into cancer.

Mammary Cancer in Feminized Male Mice.—Lacassagne's report of mammary cancer in male mice feminized by injections of estrogens has been completely confirmed.³¹ This has been done not only in strains of mice genetically cancer susceptible but also in strains of mice in which mammary cancer in the females is normally low (less than 5 per cent). It has not been possible to obtain mammary cancer in some of the strains which are cancer resistant, chiefly because they do not tolerate the estrogenic treatment; i. e., they die before the cancer age when on estrogen treatment which other strains tolerate. It has also been possible to define the optimum dose for mammary carcinogenesis following estrogenic treatment; i. e., there is a dosage level above that required for experimental estrous cycles which is not carcinogenic in these mice.

Endocrine Evidence from Spontaneous Tumors.—There is evidence from the study of gonadal tumors that endocrine imbalance may be associated with spontaneous tumors; for instance, the secretion of estrogens by testicular tumors. Of extreme interest in relation to intersexual conditions has been the finding of male dogs with mammary hypertrophy.³² These males were treated as bitches by their canine suitors. On laparotomy they were found to have tumors in testicles retained in the abdomen. This seemed to be quite a clearcut case of secretion of estrogen by testicular tumors.

Another instance is a case of multiple tumors of endocrine glands and genital organs.³³ One female

26. Each of these investigators has added a specific technic and contributed much to the development of my point of view.

27. The experiments mentioned in this article were made possible by grants from the Anna Fuller Fund, the International Cancer Research Foundation, the Committee for Research in Problems of Sex of the National Research Council, the Jane Coffin Childs Memorial Fund, and the Fluid Research Fund of Yale University.

mouse had five cancerous nodules of the mammary gland, granulosa cell tumors in both ovaries, a pituitary gland fourteen times as large as normal and the uterus in an extremely cystic and hyperplastic condition. The endocrine relation of pituitary, ovaries, uterus and mammary glands is now well established. Cystic hyperplasia of the uterus has been induced by excessive treatment with estrogens. Pituitary hypertrophy and frank pituitary tumors have also been reported after excessive estrogenic stimulation; in our colony, however, in only one strain of mice and not in others. Granulosa cell tumors of the ovary secrete ovarian hormone, for when transplanted into male mice they induce growth of the mammary rudiments of the host. This reaction will indicate smaller amounts of estrogen than required for estrous growth of the vagina, but it requires two weeks as compared with two days for the latter.

FURTHER EXPERIMENTS IN MONKEYS AND RABBITS

Meanwhile, further experiments were in progress with monkeys and rabbits in which estrogenic stimulation of mammary glands was studied. In young male monkeys with rudimentary glands it requires from six to eight months and a total dose of 80,000 international units of estrogen for growth equivalent to that of the adult nonpregnant female.³⁴ At the end of eight months of continuous estrogenic treatment of young female monkeys the mammary glands are still growing rapidly, while the uterus is small, atrophic and fibrotic—perhaps exhausted from too much estrogenic stimulation. The endometrium is so atrophic that menstruation does not follow cessation of estrogenic treatment. This is an interesting example of differential thresholds of hormone for uterus and mammary glands.

If large amounts of estrogen are injected, maintaining the hormone level considerably above normal for a long time, atypical mammary growths similar to "the witch's broom" on the willow tree may appear. One specimen was obtained from a rabbit, after injection of 5,000 international units of estrogen a week for ten months, in which three fourths of the gland was a new and quite atypical growth from a single branch of a duct of the original gland.

STUDIES OF GROWTH WITH THE COLCHICINE TECHNIC

While attempting to produce genital cancers experimentally, studies of normal growth responses to estrogens were continued. One always welcomes a chance to restudy a question with an improved technic. This opportunity opened following description of the colchicine technic, discovered by Dustin³⁵ and Lits³⁶ at the University of Brussels and advanced by studies of Ludford³⁷ in England. We³⁸ applied this technic to a study of the reaction of the genital tissues of the mouse

and monkey to estrogens. Colchicine, in the proper dose, arrests cells in mitosis, thus summarizing the dividing cells for eight or ten hours or more. This makes it possible to distinguish the part of growth in an organ (defined as increase in size) which is due to actual cell division from that which is due to other factors, such as (1) increased blood supply, (2) increased tissue fluids or (3) enlargement of cells—for all these factors are included when weights of organs are used as criteria of growth. In other words, it distinguishes hyperplasia from hypertrophy.

Seriation of Responses to Estrogen.—Several interesting points have been obtained by seriation of responses to estrogen. For instance, we are now able to seriate properly responses of tissues to estrogenic hormones. One of the first things that follows injection of estrogen into ovariectomized females is dilatation of the vessels which supply the genital organs. This begins within thirty minutes after subcutaneous injection. Vasodilatation is followed by an increase in the tissue fluids, especially in the connective tissues. Then, with the use of the colchicine technic, the beginning of cell division can be located accurately. In the castrate mouse, mitosis begins first in the lateral walls of the vagina and then in the tips of the glands of the uterus. After an initial period of glandular growth, cell division stops in the glands and they begin secreting, while cell division continues in the superficial endometrium. The wave of growth can also be quantitated in the vagina and in the "sexual skin" of monkeys.

New Evidence for Difficult Questions.—It had been suspected that a wave of growth would extend up into the uterine tubes to replace some of the cells which are eliminated in the degenerative stage of the cycle, but it had not been possible to obtain adequate evidence for such replacement. By the use of the colchicine technic it has been possible to show that at certain times these epithelial cells are replaced by cell division.³⁹ The limits of this wave of cell division in the tubes have not yet been clearly defined. Controls injected with colchicine in which tubes contained few cells in mitosis lead to the conclusion that colchicine alone does not stimulate cell division in these organs. It has been clear, however, that the uterotubal junction is often a sharp dividing line between a rapidly growing uterine mucosa and a quiescent tubal epithelium. There is some sort of growth differential at this point.

Trauma Stimulates Growth.—With the colchicine technic it has been demonstrated that stimulation of certain tissues by trauma, as well as by hormones, will induce growth. For instance, Dr. Doisy showed that sampling vaginal contents of test rats with cotton swabs would induce enough growth in the vaginal wall to give false positives in test animals. Partial growth can easily be demonstrated and the extent of cell division shown by use of the colchicine technic.⁴⁰ Also mitosis in muscle fibers of the uterus follows both hormonal stimulation and the traumatic stimulation by distention of the uterus with paraffin pellets.⁴¹ Apparently several stimuli that increase blood supply will induce cell division in tissues in which

growth is normally dominated by hormones. This need not necessarily mean that the action of estrogens is merely vasodilator.

The discoverers of the colchicine technic, in attempting to explain the great numbers of mitoses in certain tissues, have suggested that the drug may stimulate mitosis in cells which already have "a blastic potentiality." On the contrary, genital tissues of control castrate mice and monkeys injected with colchicine alone show very little cell division. Apparently they haven't the "blastic potentialities" until stimulated by the hormone or by other stimuli. The controls for these experiments give clearly negative results. When one appreciates that the vagina of a mouse stimulated by estrogenic hormone will grow from two to more than twelve layers of cells in forty-eight hours, there is no need to consider colchicine as used in our experiments a stimulator of mitosis.

SKELETAL ALTERATIONS INDUCED BY ESTROGENS

Estrogens have marked effects on tissues not primarily reproductive. Modification of the pelvis by hormone action to enlarge the birth canal in certain animals is well known. Examples are (1) the resorption of the symphysis pubis of the female pocket gopher at the time of puberty⁴² and (2) the relaxation of the pelvic ligaments of the guinea pig.⁴³ Both can be produced experimentally by injecting hormones.

Mice, males as well as females, on intensive and extended treatment with estrogens undergo complete resorption of the osseous symphysis pubis.⁴⁴ The only bond across the ventral midline is ligamentous. The resorption is so extensive that some of the ventral muscles that were previously attached to the pelvis then take their attachment from the ligamentous bond.

Formation of New Bone in the Marrow Cavities.—While the bone of the symphysis pubis is being resorbed during estrogenic treatment, new bone is being laid down in the marrow cavities of other bones.⁴⁵ In extreme experimental cases the marrow cavities have been completely replaced by formation of new bone. Then, searching in normal mice, it was found that spicules of new bone formed in untreated females toward the end of pregnancy. In normal pigeons and sparrows at the time of egg laying the marrow cavities also show evidence of new bone formation. Serum calcium and phosphorus levels did not rise appreciably in the blood of experimental mammals during this new formation, but in birds on estrogenic treatment these levels can be doubled or even tripled. The lipoids in the serum may also reach a high concentration.

When male sex hormone is injected simultaneously with effective doses of estrogen the skeletal changes are prevented, both the resorption of the symphysis pubis and the formation of new osseous tissue in the marrow cavities of other bones.⁴⁶ This explains why it requires higher estrogenic levels to induce these changes in the skeletons of males than in females.

Osteogenic Sarcomas.—Pybus and Miller (1938) observed a strain of mice in which 80 per cent of the females died with osteogenic sarcomas and in which less than 20 per cent of the males were similarly affected. The injection of estrogens in males of this strain increased the tumor incidence up to that of the females.⁴⁷ As yet, osteogenic sarcomas have not appeared in our colony of mice.

TESTICULAR TUMORS

Long-continued injections of estrogens into the A strain of mice have a very definite effect on the testes. This treatment is followed first by hypertrophy of interstitial tissues and damage to spermatogenic tubules. In some cases the tubules are entirely destroyed and the testes become nothing but hyperplastic masses of interstitial tissue.⁴⁸ They might truly be called testicular tumors.

FIBROMYOMAS OF THE UTERUS

Long-continued injections of estrogens in guinea pigs have been followed by development of multiple fibromyomas of the uterus.⁴⁹ After injection of as much as 50 rat units daily for eight months, the first sign of abnormality was the appearance of extensive bleeding from the vagina, just as in cases of uterine fibroids in women. Laparotomy showed multiple button-like fibromyomatous tumors on the peritoneal surfaces of the uterine cornua. These tumors did not extend into the lumen of the uterus. Whether bleeding from the endometrium is causally related to the tumor masses or merely a parallel development is uncertain.

In the guinea pig there is an extreme epithelial growth of the cervix with metaplasia, pearl formation and other conditions similar to those found in the monkey, but even more extreme. I know of no cases yet of cervical carcinoma in guinea pigs. It is of interest to note that extended treatment with estrogen at high levels has so far failed to produce uterine fibromyomas in mice, rats and monkeys. Why should the guinea pig seem especially susceptible to uterine fibromyomas, as apparently are Negro women?

CERVICAL CARCINOMA

Although attempts to produce cervical carcinomas in monkeys and guinea pigs have not yet been successful in demonstrating independent growths, the final proof has been obtained in mice.⁵⁰ More than twenty tumors diagnosed histologically as cervical carcinomas have appeared following long-continued estrogenic treatment. It has been possible to transplant bits of cervical carcinoma into other mice, males as well as females, and demonstrate independent growth of the cancer in the host without continued hormonal stimulation. As yet there are no cases on record of spontaneous cervical cancers in mice. It is interesting to note that mammary cancer developed in some of these animals and had to be removed surgically to allow the animal long enough life for growth of the cervical carcinoma. There is apparently a time differential between uterine cervix

and mammary glands. Also genetic susceptibility or resistance to spontaneous mammary cancer does not seem to be related to cervical carcinoma experimentally produced by estrogens.

Recently Dr. Gardner has completed a series of injections in which male hormone was injected simultaneously with estrogen. The incidence of cervical carcinoma in these mice was higher than in the series in which estrogen alone was used. Perhaps this increased incidence was due to the fact that mammary cancer does not develop in the estrogen-androgen animals and consequently these animals live longer than the estrogen series.

MAMMARY CANCER FOLLOWING METHYLCHOLANTHRENE

In some strains of mice in which mammary cancer seldom appears spontaneously, and which are resistant to mammary cancer after treatment with estrogens, mammary cancer may be induced by injecting the carcinogen methylcholanthrene.⁵¹ That the reaction may be systemic as well as local is shown by the appearance of mammary cancer following application of the carcinogen to the skin of the back.

ARE ESTROGENS CARCINOGENIC?

Many different estrogenic chemicals have been tried as to their ability to produce cancer. So far at least a dozen, including the recently discovered synthetic estrogen stilbestrol, although they have different potencies, have induced these abnormal growths.⁵²

ATYPICAL CONDITIONS PRODUCED BY ENDOGENOUS HORMONES FOLLOWING EXPERIMENTALLY PRODUCED ENDOCRINE IMBALANCE

A criticism of experiments with massive doses of estrogens has been that such enormous amounts as those injected could not possibly result from the secretion of endogenous hormone from the animal's own glands. Recently this objection has been met by ingenious work involving experimental production of endocrine imbalance.⁵³ Dr. Pfeiffer showed that in rodents there is a sexual difference in secretion of gonadotropic hormone by the pituitary. The pituitary of the male is several times more potent than that of the female. He then showed that the testis might successfully be transplanted into female mice the day after birth. These transplants, unlike the goat glands of infamous repute, become vascularized and grow normally in mice of the same inbred strain. Secretion of the transplanted testis masculinizes the female pituitary in that it induces it to secrete gonadotropic hormone at the male level. This apparently induces a hyperovarian endocrine condition and the uterus and mammary glands show atypical growths similar to those described following long-continued estrogenic injections. Therefore it is possible for endogenous hormones to produce similar changes. The inference should not be drawn that in these experiments the ovaries produced amounts of hormone equivalent to those injected in the cancer experiments. Perhaps the steady

(uninterrupted) secretion by the modified glands is the important factor. Besides, no one can tell how much of the injected hormone is destroyed by the body's defense mechanism.

GENERAL CONSIDERATIONS

I realize that "It's a long way from cancer in mice to cancer in women." I also realize that results obtained experimentally in mice may require years for confirmation in women. But surely these experiments on mice have some application clinically! And monkeys are so similar to women in reproductive function that work with them is surely at least subclinical.

The highest incidence of female genital cancer in aging persons at or after the menopause is well recognized. It is known also that ovulation usually stops after the menopause. This eliminates the possible participation of the corpus luteum hormone in periodically modifying or interrupting estrogenic stimulation. Ovarian conditions, however, especially if some cystic follicles develop, would lead one to expect a more or less continuous level of estrogenic stimulation. Therefore a hormone imbalance at this time might well be an important factor in etiology of cancer of the genital organs in women.

One of the most important problems in the matter of aging is whether or not hormone therapy should attempt to extend the function of reproductive organs by administering ovarian hormones after the menopause; that is, in the absence of clearly established pathologic changes. Use of estrogens for severe climacteric symptoms, in senile atrophy and in other conditions is well known. Moderate use of threshold doses, if not continued too long, seems entirely logical in these cases. But after the demonstration that estrogenic treatment, long continued at high levels, is followed by abnormal growths of the female genital organs, including fibroid tumors of the uterus, cervical carcinoma and mammary cancer, the following question may be asked: Is the clinician justified in prescribing enormous doses of concentrated estrogenic preparations for aging women?

Of course, there are the factors of susceptibility and resistance. Attempts to produce genital cancer with estrogens in some species of animals are still unsuccessful. A species or strain resistance seems to protect them.

The body's resistance to high doses of estrogens seems to be centered for the most part in the liver. Its function in detoxification is well established. Greene has shown in rabbits that experimental damage to the liver, similar to that which occurs in toxemias of pregnancy, decreases the effective dose of estrogen and shortens the time of appearance of mammary cancer and that an experimentally induced mastitis may produce similar results.

Again it may be pointed out that in some cases aging women have already been given massive doses of estrogen without subsequent appearance of genital cancer. The answer to this lies in an understanding of cancer incidence. When groups of mice are injected with optimum doses of estrogen for induction of mammary cancer, only a certain percentage will die of cancer. Something of genetic susceptibility or resistance to cancer in mice is known, for half a dozen generations can be bred in a year, but very little is known as yet of genetic susceptibility to cancer in human beings.

Then there is the matter of time lag or interval between a stimulus and the development of cancer, and

there is much evidence to show that in man this may be a matter of years, just as with x-ray burns and radium poisoning.

I do not wish to attach an undue significance to these experimental results with estrogens. It seems to me, however, that they do indicate the possible danger of long-continued high levels of a hormone which is a natural constituent of the normal female body. These results also indicate that, unless an individual is especially susceptible, there are levels of estrogenic treatment which, so far as is known at present, are below the carcinogenic level. If therapeutic levels can be established within a safe range, the danger can be minimized.

333 Cedar Street.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS.

HOWARD A. CARTER, Secretary.

FISCHER MODEL S SHORT WAVE UNIT ACCEPTABLE

Manufacturer: H. G. Fischer and Company, 2323 Wabansia Avenue, Chicago.

The Fischer Model S Short Wave Unit is designed for medical and minor surgical diathermy. It combines the cabinet and portable features, since the section containing the short wave mechanism can be removed from the cabinet and carried. Accessories that have been tested include cuff and inductance cable electrodes. Electrosurgical accessories are also available but were not tested. The shipping weight is 122 pounds and the net weight 92 pounds.

Fischer Model S Short Wave Unit.

The apparatus is provided according to order with a 6 or 12 meter wavelength and employs two Westinghouse No. 471 oscillator tubes and two rectifier tubes in a tuned plate, tuned grid circuit. A choke coil is used in the primary circuit to reduce radio interference. The unit is ventilated by air convection. It operates on 105-120 volts, 60 cycle alternating current.

The firm submitted evidence for the claim that with an electro-motive force of 115 volts and a full input load of 755 watts the

Inductance coil technic....	99.4	107.7	98.3	98.8

output is 350 watts. The Council confirmed this power output by the conventional lamp load method, using four 100 watt tungsten filament bulbs in parallel. The final temperature of the outside windings of the transformer came within the limits of safety after the unit had been operated at full load for two hours.

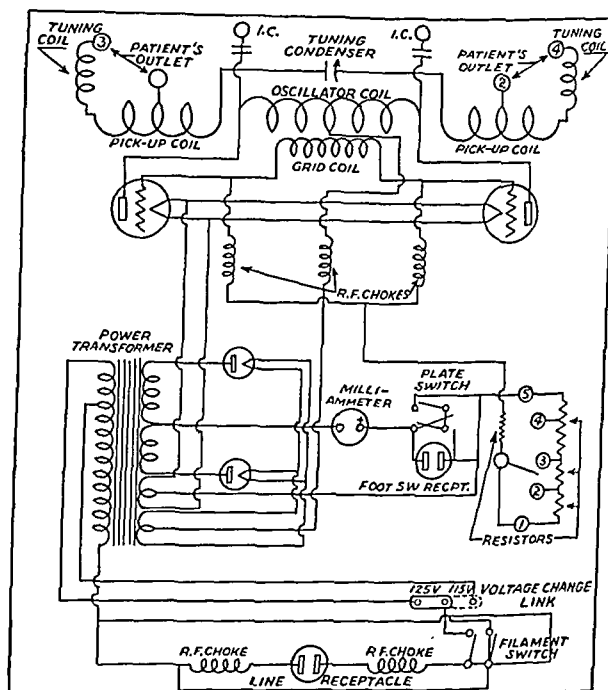

The Model S has a similar circuit to the Council-accepted Model PC (THE JOURNAL, Dec. 24, 1938, p. 2393) and therefore the same evidence for the power of the unit to produce heat deep within human tissue was used for the Model S. The data are given in the accompanying tables.

The apparatus was reported to give satisfactory clinical service in investigations conducted for the Council.

Schematic diagram of circuit.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Fischer Model S Short Wave Unit, as used with the cuff and coil electrodes, for inclusion in the Council's list of acceptable devices.

EREX HYPO-ALLERGENIC COVERS (Pillow, Mattress, Crib Covers) ACCEPTABLE

Manufacturer: Erex Hypo-Allergenic Products Company, 763 Boatman's Bank Building, St. Louis.

The Erex Hypo-Allergenic Pillow, Mattress and Crib Covers are intended to protect individuals allergic to dust from pillows and also to provide general sanitation of the pillow and its protection from perspiration. The covers are made of a rubberless fabric called "Revolite." The pillow covers are 21 by 28 inches in size and are intended to be covered by regulation type pillow cases. The mattress covers are available in twin or full bed size.

Two samples of covers were submitted to the Council, in which binding tape was used along the seams. In one, a coated tape similar to the Erex fabric was used, and in the other the customary "stay" tape. The stitching is of the lock-stitch type,

claimed to be a tighter stitch than the chain type. The pillows are closed by an invisible slide fastener and there is a "cup flap" to protect the slide fastener opening and help keep the enclosed pillow in proper place.

The firm claims that the cover is dust proof, perspiration proof and sanitary. It is advocated for asthma, hay fever and sinus sufferers. According to the producers, the covers launder well and will remain permanently soft and pliable. Evidence was submitted by the firm to show the resistance of the covers to heat and cold and a variety of chemical agents.

The covers were investigated by the Council and found to be as satisfactory as such covers probably can be made. The material composing the covers is impervious and stands washing as described in the printed matter submitted with it. When they are filled with water there is practically no leakage along the seams within several minutes. There is, however, the unavoidable leakage around the slide fastener opening. This leakage of water cannot be prevented by any flap, but the manufacturer's idea of using the cuplike flap to extend around the end of the pillow under the slide fastener makes an effective seal against dust.

The Council on Physical Therapy voted to include the Hypo-Allergenic Covers on its list of accepted devices.

Council on Pharmacy and Chemistry

COUNCILS' COMMITTEE ON CONTRACEPTIVES

THE FOLLOWING REPORT WAS PREPARED UNDER THE AUSPICES OF THE COUNCILS' COMMITTEE ON CONTRACEPTIVES AND PUBLICATION HAS BEEN AUTHORIZED.

PAUL NICHOLAS LEECH, Secretary
COUNCIL ON PHARMACY AND CHEMISTRY.
HOWARD A. CARTER, Secretary
COUNCIL ON PHYSICAL THERAPY.

RUBBER SHEATHS

The condom is perhaps the simplest, most widely used contraceptive measure. When properly tested sheaths are used skillfully, the patient obtains practically complete protection. Authorities also agree, in general, that the condom is the most useful of all methods for venereal disease prophylaxis. The review by Cautley, Beebe and Dickinson¹ on the quality and effectiveness of rubber sheaths in prophylaxis was undertaken because of the widespread use of this article.

The chief difficulty of the method lies in the existence of inferior articles. Methods of manufacturing have improved considerably in the past few years when the dipping in crape rubber solution was replaced by the liquid latex method. Nevertheless a large portion of the output by the manufacturers was unreliable, as shown by careful testing. Tests conducted by Voge² of more than 2,000 condoms of various brands demonstrated that a large percentage of condoms were imperfect according to the Voge technic of testing, 50 per cent containing flaws.

The Food and Drug Administration has informed manufacturers that:

Regardless of the nature of the products or methods by which they are used, all articles intended as venereal disease preventives are subject to the provisions of the act [Federal Food and Drug Act].

It is the consensus of present-day medical opinion that no article which depends on its chemical action for its preventive properties is sufficiently effective against all venereal diseases to justify an unqualified claim for the prevention of venereal disease. Other articles depending for their prophylactic effect on preventing contact with infecting organisms should be free from defects.

Preventive claims should be unambiguous and limited to the disease or diseases against which the article is known to be effective. The directions should be such as to insure suitable use.

In the year ended June 30, 1939, the sampling and examination of prophylactics by the Department of Agriculture resulted in the seizure of seventy-five consignments. This department is continuing to collect and examine a great many more samples. This action has resulted in some firms closing down their plants

1. Cautley, Randolph; Beebe, Gilbert W., and Dickinson, Robert L.: Rubber Sheaths as Venereal Disease Prophylactics, *Am. J. M. Sc.* 1935: 155 (Feb.) 1938.

2. Voge, C. I. B., quoted by Cautley, Beebe and Dickinson.¹

to install new machinery and improve their manufacturing processes. The more recent investigations have shown that imperfect samples are still encountered, but that the market contains a far higher quality rubber sheath than at any other time.

It is therefore anticipated that in the future most condoms purchased on the market will conform to the desired degree of quality which would make for a fairly reliable method for venereal prophylaxis as well as for purposes of therapeutic contraception.

Council on Foods

ACCEPTED FOODS

THE FOLLOWING ADDITIONAL FOODS HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO ACCEPTED FOODS.

FRANKLIN C. BING, Secretary.

FOODS FOR SPECIAL DIETETIC PURPOSES (See Accepted Foods, 1939, p. 295).

Northwest Powdered Fruit Laboratories, Inc., Yakima, Wash.

Po-AP, a granular form of powdered dried apple pulp from several varieties of apples. This product is useful in the dietary management of diarrhea.

Analysis (submitted by manufacturer).—Moisture 4.5%, total solids 95.5%, ash 1.6%, fat (ether extract) 3.4%, protein (N \times 6.25) 1.5%, crude fiber 4.2%, reducing sugars before inversion 53.0%, sucrose [(total reducing sugars after inversion minus reducing sugars before inversion) \times 0.95] 18.1%, pectic acid (alcohol precipitate) 3.9%, total carbohydrates other than crude fiber (by difference) 84.8%, iron (Fe) 0.00275%, calcium (Ca) 0.0204%, magnesium (Mg) 0.0282%, phosphorus (P) 0.0029%, sulfur (S) 0.032%, sodium (Na) 0.107%, potassium (K) 0.847%, chlorides (Cl) 0.21%, copper (Cu) 0.00077%, lead (Pb) none, arsenic (As₂O₃) 0.00015 grain per pound of apple powder, sulfur dioxide (SO₂) 0.005%.

Calories.—3.5 per gram; 99 per ounce.

MILK AND MILK PRODUCTS (See Accepted Foods, 1939, p. 230).

Helm Goat Milk Products, Grass Lake, Mich.

HELM'S BRAND DEHYDRATED GOAT'S MILK, a spray-dried, homogenized whole goat's milk.

Analysis (submitted by manufacturer).—Moisture 1.0%, total solids 99.0%, ash 6.5%, fat (ether extract) 29.0%, protein (N \times 6.38) 25.0%, lactose (by difference) 38.5%.

Calories.—5.2 per gram; 148 per ounce.

VEGETABLES (See Accepted Foods, 1939, page 345).

General Foods Corporation, New York, product distributed by Frosted Foods Sales Corporation, New York.

BIRDS EYE BRAND QUICK-FROZEN GREEN PEAS, quick-frozen, ready-to-cook, green peas, conforming to the U. S. D. A. tentative standards for frozen peas, as U. S. Grade A (fancy).

Manufacture.—The peas are packed in a number of plants located in different sections of the United States. Trained field representatives exercise control over the selection, cultivation and harvesting of the crops, as well as the packing and freezing operations in all plants. The method of processing has been described briefly in the report of the Council on Foods [Rose, Mary S.: The Effect of Quick Freezing on the Nutritive Values of Foods, *J. A. M. A.* 114:1357 (April 6) 1940] as the indirect contact, multiple plate method, with multiple plate freezers. The blanched peas are packed in cellophane-lined cartons which are sealed in wax paper. Cartons of the finished product are transported in specially designed refrigerator cars in which the temperature is reduced to from 15.6 to 11.1 C. When the foods reach their destination they are stored at —17.8 C. until they are delivered to a distributor. Refrigerator cases are used in retail stores and in institutions to maintain the products at low temperatures. The Frosted Foods Sales Corporation provides dealers and institutions with detailed instructions for the care of the cases.

Analysis (submitted by manufacturer).—Average: Moisture 81.2%, total solids 18.8%, ash 0.6%, fat (ether extract) 0.5%, protein (N \times 6.25) 5.2%, crude fiber 2.1%, sucrose 4.8%, reducing sugars 0.00, starch 2.3%, carbohydrates other than crude fiber (by difference) 10.4%. Range: Moisture 80.0 to 82.8%, total solids 17.2 to 19.8%, alcohol insoluble solids 12.5 to 18.0%, ash 0.5 to 0.6%, fat (ether extract) 0.4 to 0.6%, protein (N \times 6.25) 4.9 to 5.5%, crude fiber 1.8 to 2.3%, sucrose 4.4 to 5.4%, reducing sugars 0.00, starch 1.8 to 3.2%, carbohydrates other than crude fiber (by difference) 9.6 to 10.8%.

The firm reports (1939) the vitamin content to be as follows (fresh basis): vitamin A from 3.0 to 5.5 micrograms of beta carotene (equivalent units) per gram, vitamin B₁ from 1.0 to 1.5 international units per gram, vitamin G (riboflavin) from 0.7 to 1.0 international units per gram, vitamin C from 0.13 to 0.26 mg. of Sherman-Bourquin units per gram, vitamin C from 0.65 to 1.30 international units per gram.

Calories.—Average: 0.67 per gram; 19.03 per ounce. Range: 0.62 to 0.68 per gram; 17.6 to 19.3 per ounce.

SATURDAY, MAY 25, 1940

THE PLATFORM OF THE AMERICAN MEDICAL ASSOCIATION

The American Medical Association advocates:

1. The establishment of an agency of the federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy.
2. The allotment of such funds as the Congress may make available to any state in actual need, for the prevention of disease, the promotion of health and the care of the sick on proof of such need.
3. The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility.
4. The development of a mechanism for meeting the needs of expansion of preventive medical services with local determination of needs and local control of administration.
5. The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration.
6. In the extension of medical services to all the people, the utmost utilization of qualified medical and hospital facilities already established.
7. The continued development of the private practice of medicine, subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability.
8. Expansion of public health and medical services consistent with the American system of democracy.

THE PHARMACOPEIAL CONVEN- TION OF 1940

Last week approximately 500 representatives of medicine, pharmacy and related sciences assembled in Washington to constitute the decennial U. S. Pharmacopeial Convention. Ten years has elapsed since the last previous convention, which THE JOURNAL described as a farcical assemblage if considered from the point of view of scientific progress. Industrial interests overwhelmed that convention with representatives; the ratio of pharmaceutical interests to scientific medicine was about five to one. The results were fortunately not as disastrous as then seemed likely because a number of faithful and competent workers, appointed to the Revision Committee, sacrificed time and effort to bring forth a creditable pharmacopeia.

The Pharmacopeia is vital to physicians because it establishes the legal standards under which the United States government enforces the purity of official drugs in interstate commerce. Because of its particular significance to the practice of medicine, the American Medical Association through its Board of Trustees, its Council on Pharmacy and Chemistry and THE JOURNAL, has always urged efforts toward the development of the best pharmacopeia possible for the needs of modern medicine. This year, by editorials in THE JOURNAL and by correspondence, every reputable medical school and every state medical association was urged to send delegates. The delegation was much larger than ten years before but still not as large as it should have been. The spirit of the convention was far different from that which prevailed previously. The report of the president of the convention, Dr. Walter A. Bastedo, was followed by papers by Dr. Morris Fishbein of the American Medical Association delegation, by Mr. E. F. Kelly, representing the American Pharmaceutical Association delegation, and by Mr. W. G. Campbell, commissioner of the Food and Drug Administration. Two of these papers emphasized the unwieldy character of the convention and the need for modernizing its methods of procedure. These suggestions were received cordially by the reference committee to which the papers were referred and endorsed by the convention. The delegation of the American Medical Association presented, and the convention adopted, the following resolution:

Resolved, That the President and the Board of Trustees be authorized to appoint a committee of nine, consisting of four physicians, four pharmacists and one representative of a governmental agency, and including the president, the secretary and the chairman of the revision committee, ex officio, to make a revision of the constitution and by-laws of the United States Pharmacopeial Convention; and

That this revision be submitted to the convention at a special session to be called by the Board of Trustees not more than two years from the date of adjournment of this session; and

That the following principles be considered in the preparation of this proposed revision:

1. The development of a representative body of a size capable of functioning efficiently.
2. Suitable and proportional representation for medicine, pharmacy, dentistry, veterinary medicine, governmental agencies and manufacturing pharmacy.
3. Selection of well qualified experts to undertake the necessary periodic revisions of the Pharmacopeia.
4. Selection of a governing body or board of trustees with continuous overlapping terms of office to provide for continuity of policy and action.
5. Revision and publication every five years with interim supplements.
6. Establishment of fundamental criteria for admission of drugs and preparations to the Pharmacopeia.
7. Establishment of a full time executive staff without personal affiliation with any private agency.

Mr. Campbell emphasized the fact that establishment of standards for drugs was wholly within the purview of the convention and that the Food and Drug Administration had no disposition to dominate in any way the

action of the Revision Committee of the Pharmacopeia unless there should arise some emergency in which public health would demand action. Even in this event, he said, any action would be taken only after consultation with the Pharmacopeial authorities.

The convention also changed a number of the by-laws of procedure; the changes will presumably be in effect until a new constitution and by-laws are adopted. Hereafter each delegation will be entitled to only one vote. This was in conformity with the suggestions which had been made repeatedly by *THE JOURNAL*.¹ It was tacitly understood that the Committee on Revision would be composed of one-third medical representatives and two-thirds pharmacists, but that the medical representatives would have full control on questions of therapeutic scope.

Dr. C. W. Edmunds, who has served long and well as a member of the Revision Committee, was chosen president of the convention for the next decennial period. The Board of Trustees (composed of two physicians and three pharmacists) now consists of Dr. Walter A. Bastedo, Dr. Morris Fishbein, editor of *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, Mr. Robert L. Swain, editor of *Drug Topics* and *Drug Trade News*, Mr. E. F. Kelly, secretary of the American Pharmaceutical Association, chairman, and Dr. E. E. Little, dean of the Rutgers School of Pharmacy. The members of the Revision Committee, whose names appear elsewhere in the news columns of *THE JOURNAL*, chose Dr. E. Fullerton Cook to continue in the important position of chairman of the Revision Committee. Dr. Cook has ably conducted the revision of the Pharmacopeia in the last decade and a half.

The 1940 convention may well stand in medical and pharmaceutical history as a turning point toward progressive procedure in the formulation of this important compendium. If a new constitution and by-laws are adopted in accordance with the instructions of the convention, work will be facilitated, self seeking will be discouraged and a scientific spirit will be maintained. No longer will there be the difficult task of securing sufficient representation in medicine and progressive pharmacy for a meeting in which predatory interests might otherwise overrule the decisions. Proportionate representation will undoubtedly be provided on a scale which will develop a smaller and more efficient assemblage. In the future, no doubt, members may be chosen for the Revision Committee on the basis of competence primarily rather than because of ability to attend the convention. The best men available should aid in the revision. The Pharmacopeial Convention of 1940 represents the fruitful union of the most progressive elements of both medicine and pharmacy and should result in the production of the best pharmacopeia in the world.

CHEMOTHERAPY OF INFECTIOUS DISEASES

In 1904 Ehrlich summarized the aims of chemotherapy: "What we seek is 'specific chemotherapy,' that is, we are in the search of a drug which should be capable of destroying certain parasites without at the same time causing too much damage to the host." Since that time chemotherapy has accomplished notable successes in the treatment of diseases caused by protozoa and spirochetes and more recently by other bacteria. The use of organic arsenical compounds in the treatment of syphilis, of plasmochin and atabrine in malaria, of quinoline derivatives in ameba amebiasis and of antimony compounds in the treatment of leishmaniasis is well established. In the case of bacterial disease the problem proved to be much more difficult because the organisms are much less differentiated. Koch's failure to cure guinea pigs infected with anthrax by injection of mercuric salts discouraged, at least temporarily, much research in this field.

The preparation by Gelmo in 1908 of the compound para-aminobenzenesulfonamide in the course of a purely scientific research not at all concerned with problems of chemotherapy resulted, nevertheless, in a renewed interest in the search for new chemotherapeutic agents. Hörlein, Dressel and Kothe of the I. G. Farbenindustrie prepared new textile dyes from azo compounds containing sulfonamide groups. Eisenberg demonstrated the bactericidal action of certain azo compounds in vitro and employed chrysoidin for chemotherapeutic purposes. American investigators, Heidelberger and Jacobs, linked dihydrocupreine with diazo compounds obtained from aromatic amines, including para-aminobenzenesulfonamide, and found that many of the azo compounds thus formed exhibited bactericidal properties in vitro but not in vivo. A number of azo compounds were found in the laboratories of I. G. Farbenindustrie to possess bactericidal properties in vitro. Compounds containing the sulfonamide group were found to be effective against streptococcal infection in animal experiments. The chemists Klarer and Mietzsch synthesized sulfonamide containing azo compounds, and Domagk demonstrated that one of these products was effective in preventing death in mice infected with lethal doses of streptococci. Their collaboration led to the development of a product patented as "Prontosil" and somewhat later to "Prontosil Soluble." At about the same time Trefouel and his associates in France established that a number of azo dyes prepared from para-aminobenzenesulfonamide but of different physical and chemical properties had an antistreptococcal action like that of "Prontosil." They have advanced the hypothesis that all the active azo dyes, including "Prontosil," were reduced in the organism to sulfanilamide. This led them to the important discovery that the simple

1. The Call for the Pharmacopeial Convention of 1940, editorial, J. A. M. A. 112: 1969 (May 13) 1939. Physician and Pharmacopeia, *ibid.* 113: 2323 (Dec. 23) 1939.

EDITORIALS

ss compound sulfanilamide was itself highly active therapeutic agent in experimental streptococcal infection. Domagk's contribution, as Heubner points out, consists in establishing the fact that of the many substances the derivatives of sulfanilamide alone possess the property of favorably influencing streptococcal infection in the mouse, the rabbit and man. The dramatic results obtained with sulfanilamide in many instances in a variety of streptococcal infections such as puerperal fever, meningitis, septicemia, erysipelas, scarlet fever and osteomyelitis and in gonorrhea are now common knowledge attested by an overwhelming literature. The new derivative sulfapyridine has been found to be strikingly effective in pneumococcal pneumonia. The most recent derivative, sulfathiazole, appears to be as effective against pneumococcal infection as sulfapyridine but is superior to both sulfapyridine and sulfanilamide against staphylococcal infection.

Empiricism, however, has definite limitations. It is realized that further knowledge can come only from understanding the mode of action of these compounds. This subject was editorially discussed in THE JOURNAL,¹ but for a more detailed exposition one should consult the reviews by Domagk,² by Marshall,³ and a recent one by Heubner.⁴ A genuine bactericidal effect of sulfanilamide on the cocci has not been demonstrated. The effect is rather that of arrest of growth, due possibly to disturbance of metabolism or to interference with the capsule formation of the cocci. R. L. Mayer⁵ pointed out that the frequent appearance of methemoglobin in the blood of animals and patients treated with sulfanilamide suggests the formation in the body of a product of the drug responsible for the formation of methemoglobin. He advanced the hypothesis that the bactericidal effect is due not to sulfanilamide but to the same oxidative product which oxidizes hemoglobin to methemoglobin. This theory is further developed by Shaffer,⁶ who states that the probable mode of action of sulfanilamide is that the drug provides a mechanism by which the sterilizing oxidation intensity of molecular oxygen is applied merely at its maximum to bacteria and unfortunately also, to some extent, to host cells. The present status of our knowledge is summed up by Marshall in his review of the pharmacology of sulfanilamide: "No satisfactory explanation of the mechanism of action has been found." There is, however, little doubt that the advent of sulfanilamide has initiated a true renaissance of bacterial chemotherapy.

HEPARIN

As a result of the rapidly developing information concerning this substance during recent years, heparin, from being a rather unique anticoagulant with limited laboratory application, has become a promising clinical adjunct. The isolation of a highly purified product has contributed to the advance in our knowledge of this substance. The rapidly accumulating information regarding heparin has recently been reviewed by the Scandinavian investigator Jorpes.¹

With the purified product available, organic chemists have made progress in establishing the chemical structure of the heparin molecule. Thus Charles and Todd² have studied the crystalline barium salt of heparin which was isolated from heparin preparations made from beef lung, beef liver and beef intestine. All these crystalline barium salts are similar in their composition and physiologic potency. Charles and Todd, after careful observations of the chemical behavior of heparin and on the basis of previous work, have concluded that heparin is a mucoitin sulfuric acid in which the fundamental structural unit consists of two molecules of acetyl glucosamine and two molecules of glycuronic acid. Each unit also contains five sulfuric acid groups, which impart strongly acidic properties to heparin; physiologic inactivation follows the removal of the sulfate groupings.

The provision of highly purified preparations of heparin for experimental study encouraged clinical use of this substance. Jorpes has attempted to demonstrate heparin directly in the walls of the large blood vessels by the use of toluidine blue, which stains heparin strongly metachromatically. Within a few hours after large vessels have been immersed in a dilute solution of toluidine blue there results a purple staining of the vessel walls, most marked near the lumen. The old idea that heparin is localized in the vascular system thus appears in a new form. Further study in collaboration with histologists pointed to the mast cells of Ehrlich as responsible for the metachromatic purple coloration obtained with the staining dye. Strongly suggestive proof was then obtained that the granules of the mast cells of Ehrlich consist of heparin. Moreover, a rather good correlation was found between the histologically demonstrated content of mast cells of various tissues and organs and the content of heparin which they yield. There is other supporting proof for the conclusion that the metachromatic granules in the mast cells of Ehrlich consist of heparin. These cells, by virtue of their position around the capillaries and certain of the small blood vessels, apparently have the opportunity of emptying the contents of their granules directly into the blood stream.

The isolation of relatively pure heparin³ has led to an extensive examination of the relationship of this anticoagulant to the problem of thrombosis, particularly, by Best and his collaborators at Toronto.¹ It was demon-

strated that heparin greatly inhibits the formation of thrombi produced in animals by mechanical or chemical trauma to the intima of large exposed veins. The ability to produce coronary thrombosis in dogs by means of sodium ricinoleate was also greatly diminished in heparinized animals, as compared to control dogs which did not receive heparin. These successful experiments have stimulated the use of pure heparin in clinical cases of thrombosis and remarkable results have been reported at the Toronto General Hospital and in Stockholm.³ Heparin has been employed postoperatively with a high degree of success; pulmonary embolism or thrombophlebitis was not observed in instances in which these complications might ordinarily be expected. Although it is somewhat difficult to evaluate postoperative treatment for the prevention of thrombosis, more direct evidence of the value of heparin may be obtained in the treatment of an existent thrombus. Striking claims have been made in the Swedish clinics⁴ for the value of heparin in the treatment of thrombosis in the main trunk of the central vein of the retina, and subsequent definite return of visual acuity has been reported. Similar efficacious results with heparin are reported in vascular surgery.¹ In recent preliminary publications in *THE JOURNAL*,⁴ suggestions have been made for the use of intravenous heparin drip, in conjunction with sulfapyridine, in the treatment of subacute bacterial endocarditis. The prevention of embolus formation greatly diminishes the nidus for growth of bacteria and vegetations.

Future clinic work may definitely establish the value of heparin in clinical thrombosis, coronary thrombosis, thrombosis of the large veins and thrombophlebitis. Heparin, like many other therapeutic substances, is the product of the combined efforts and interests of the physiologist, the biochemist and the clinician and has now passed from pure physiology to medicine by way of biochemistry.

Current Comment

THE ROCKEFELLER FOUNDATION

The review of the 1939 work of the Rockefeller Foundation presented by its president, Raymond B. Fosdick,¹ clearly illustrates the interdependence of scientific work throughout the world. Hampered as the work of this foundation now is by factors beyond its control, the report exemplifies the many ways in which expenditures trifling in comparison with armament expenditures can influence the scientific, medical and social lives of vast numbers of people. The work supported by the foundation in South America against the dreaded malaria-carrying mosquito *Anopheles gambiae*, imported from Africa, represents a campaign

the outcome of which is of importance to the entire continents of South and North America. Similarly the studies on yellow fever actively initiated by the foundation as well as numerous other public health activities and assistance in other branches of medical science are of profound importance to the public health. The foundation also gives material encouragement in the fields of natural science, the social sciences, library work, the educational activities of radio, the humanities, health and educational activities abroad, especially in China, and in its assignment of fellowships throughout the world may be serving to keep alive some spark of international cooperation which will help in reconstruction at some later date.

FOURTH OF JULY FIREWORKS INJURIES

This year the American Medical Association, as in the previous three years, will compile its annual summary of fireworks injuries resulting from the celebration of the Fourth of July. Although several states have adopted effective antifireworks legislation, the injuries in 1939 nevertheless numbered 5,560 and the deaths thirteen. These figures clearly indicate that there can be no relaxation of efforts to prevent such unnecessary accidents. Hospitals throughout the country are therefore again asked to cooperate in filling out the questionnaires which they will shortly receive to list the deaths and injuries from this source.

FOOD AND DRUG ADMINISTRATION TRANSFERRED TO FEDERAL SECURITY AGENCY

President Roosevelt's Reorganization Plan No. IV, which was commented on in a previous issue of *THE JOURNAL*,¹ becomes effective June 11. On that day, pursuant to the President's plan, the Food and Drug Administration and its functions, except those relating to the administration of the Insecticide Act of 1910 and the Naval Stores Act, will be transferred from the United States Department of Agriculture to the Federal Security Agency. Thereafter the Administration will function as a separate unit under the direction and supervision of the Federal Security Administrator. The chief of the Food and Drug Administration will be known as the Commissioner of Food and Drugs. On the same day St. Elizabeths Hospital, Freedmen's Hospital, Howard University and the Columbia Institution for the Deaf will also be transferred to that agency. For years the American Medical Association has recommended, and in its Platform it continues to advocate, the establishment of an agency of the federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy. The President's Reorganization Plan No. IV and the prior transfer of the United States Public Health Service to the Federal Security Agency would seem to indicate an attempt by the President to gather together under one agency the diverse medical and health functions of the federal government.

ORGANIZATION SECTION

VOLUNTARY HEALTH INSURANCE IN THE NETHERLANDS

MOLLEURUS COUPERUS, M.D.
CHEHALIS, WASH.

During the summer of 1939 Dr. J. J. Couperus of Rio Vista, Calif., and I visited the Netherlands and while there investigated the system of voluntary sickness insurance which is in operation there. We received hearty cooperation in the accomplishment of this task from the officials of the Association for the Advancement of Medicine in the Netherlands, the official medical organization of Holland.

Prior to 1912 the business of offering sickness insurance to the low income class of the Netherlands was entirely in the hands of private and mutual insurance companies. There was a deplorable lack of cooperation and understanding between the various groups interested in this insurance, and conditions gradually became such that the medical organization of the Netherlands decided to take the leadership in solving this important problem.

In 1912 the Association for the Advancement of Medicine succeeded in unifying sickness insurance by drawing up a plan for an acceptable health insurance policy. Private companies who adopted the suggested policy could be endorsed by the association, and in addition the association established a sickness insurance company of its own. The insurance policy as recommended to the private companies was identical with the policy of the insurance company fostered by the medical association. Since the year of its inception there have been many changes in the original plan, but in the end this plan of voluntary sickness insurance for the low income group has become an integral part of the life of the people of the Netherlands.

GOVERNMENT SEEKS CONTROL OF INSURANCE PROGRAM

In 1925, when a cabinet that was socialistically minded came into power, the government of the Netherlands made an attempt to gain control of the sickness insurance program. After investigation, however, it was found that the administrative expenses, which had been, and still are, from 8 to 10 per cent of the total receipts, would be increased about fourfold when in government hands. Consequently the plan was abandoned and the medical association continued to regulate the health insurance business. However, the government has its independent industrial accident insurance. The low income insurance plan does not treat any sickness which would fall under government industrial accident insurance.

Of the eight million population of the Netherlands, four million, or 80 per cent of the low income group, are voluntary subscribers to this health insurance plan. One and a half million of these are insured directly by the medical association, while the remaining two and a half million are insured by private companies endorsed by the medical association. There are 4,200 practicing physicians in the Netherlands, and more than 4,000 of these have voluntarily enrolled with the medical association to serve on this insurance program. When a physician decides to participate in the plan he applies to the nearest insurance office; his application is acted on within a month, and if he is a member

of the medical association he is accepted. If he is not a member, it must be established that his professional conduct is above reproach. However, at present all practicing physicians in Holland are members of the medical association, in spite of the fact that the annual dues amount to 60 guilders (about \$32). After the physician has been placed on the roster of insurance physicians he is given a list of the insured who have selected him as their family physician. The average number of patients a physician has on his list usually does not exceed 1,750. The maximum number of individual patients on any physician's list, except under very unusual circumstances, may not exceed 3,000. For those patients who are on his list, the physician receives a minimum of 3.50 guilders (\$1.85) per individual annually, payable quarterly. Physicians who live in the country are allowed 5 or 6 guilders (\$2.65 or \$3.18) a year per patient; extra mileage and the furnishing of drugs to the patient accounts for the difference in the fee. The physician has practically no report blanks to fill out concerning his patients. Specialists are paid according to a special fee schedule previously agreed on between them and the insurance company.

Any one who has an income of less than 2,100 guilders (\$1,113) a year if single or 3,000 guilders (\$1,590) if the head of a family, may enroll as a subscriber to the sickness insurance plan for the low income group. The insurance fee for a single individual is 25 cents a week. This entitles him to professional care by his family physician, the services of a specialist when ordered by the general practitioner, surgical treatment, x-ray service, laboratory work, drugs, ambulance service when required, and the use of such medical and surgical appliances as may be needed, including wheelchairs and crutches. For an additional 8 cents a week he is also insured for hospital expenses (ward accommodation) for a period of six weeks; by paying a slightly higher fee he may obtain complete hospital coverage for an indefinite period. There has been a definite tendency on the part of the insurance company to supply only the latter type of hospital insurance. The cost of complete medical and hospital insurance for a family of average size is about 90 cents a week; as soon as a child reaches the age of 16 the parents must pay a separate fee for that child. Those who have a chronic or recurrent illness before joining the insurance plan must pay a higher fee than if they were in normal health. Obstetric service is included in the plan, but there is a short waiting period before this part of the insurance becomes effective, and the insurance premium is slightly higher during the months in which the woman is pregnant. Eyeglasses are furnished only once in two years on the prescription of a physician.

The country is divided into some sixty insurance districts, corresponding quite closely to the areas of the local medical societies; each district has its own board of physicians and lay members. The insurance premium is collected each week by salaried messengers.

This insurance plan for the low income group in the Netherlands may be called a distinguished success. With only one exception, all physicians whom we ques-

tioned heartily endorsed the plan. They felt that the position of the physician was improved with regard to working conditions as well as to payment for services rendered to those in this group. They also stated that the low income group received better medical care than it had before the adoption of this plan. One physician, who was a specialist in internal medicine and not an insurance physician, stated that he believed that the number of patients allowed per physician should be smaller and that the physician's fee per patient should be larger. When we asked the patient about the insurance scheme we found undivided and enthusiastic support of the plan. At the headquarters of the Association for the Advancement of Medicine the opinion was given that the plan has worked well for all concerned, and the results of our investigation supported that opinion.

An insurance plan to cover those of larger incomes, the middle class, had been in preparation for a number of years and was ready for operation in the fall of 1939. Those whose taxable income does not exceed 4,000 guilders (\$2,120) a year for a single individual or 5,000 guilders (\$2,650) for a family may join this plan. The insured receives the services of his family physician, a maximum of ten calls a year at a specialist's office, hospitalization, drugs, ambulance service, and the use of clinical laboratories (including x-rays) but not dental care or obstetric service. However, after one year of membership, surgery necessitated by pregnancy is allowed, such as cesarean section or surgery for rupture of the uterus. For this insurance the patient pays an enrolment fee of 1 guilder (53 cents) and an annual basic contribution of 50 guilders (\$26.50) for a single male, 60 guilders (\$31.80) for a single female, 84 guilders (\$44.50) for a man and his wife, 110 guilders (\$58.30) for a family with one child, 135 guilders (\$71.55) for a family with two children and 15 guilders (\$7.95) for an additional child; these fees are payable in advance in monthly instalments. After one has joined the insurance plan there is a waiting period of three months, during which the insured must pay his own medical bills; the insurance premium paid during that period is placed in a special fund to the credit of the insured. After the waiting period is past, all

medical bills which the insured incurs are forwarded by him to the insurance office, which pays the doctor, druggist and hospital. To counteract the tendency to seek unnecessary medical service, part of the annual premium is put to the credit of the insured in a special fund. If the medical bills remain below two thirds of the annual premium, whatever amount is left of the premium will be added to the personal reserve fund of the insured. When this fund contains 100 guilders (\$53) interest is paid on it; when it reaches the figure of the annual premium the excess is deducted from the next premium. Should the insured decide to discontinue his sickness insurance policy, the money in his personal reserve fund will be returned to him by the insurance company. If, during any year, the medical bills of the insured exceed his premium as well as his reserve fund, he is expected to pay a small percentage of this excess amount. For example, should the medical bills for the year reach 300 guilders (\$159) the insured pays an extra assessment of 16.50 guilders (\$8.75) above his basic annual premium. If his medical bills should total 1,000 guilders (\$530) he must pay an extra 79.50 guilders (\$42.15). Thus the insured has a perpetual interest in keeping his medical bills at a minimum.

Under this plan of sickness insurance for the middle class the physician is paid his customary fee for private patients. The physician sends an itemized statement to the patient, who has an opportunity to check both the services rendered and the fees charged; he must forward the bill within a month to the insurance office.

The insurance company of the medical association also is planning to take over the medical care of the destitute. In the past these unfortunates have been cared for by physicians who entered the lowest bid to the city or county for the medical care of their poor. Under the new plan the city or county pays the insurance company for each patient a premium slightly less than what is paid by other members of the low income group insurance plan. For this the poor man receives complete medical care and has free choice of his physician. It is expected that the plan will please the city and county governments, the patients and the medical profession.

1037 Market Street.

NATIONAL CONFERENCE ON MEDICAL NOMENCLATURE

Held in Chicago, March 1, 1940

DR. HAVEN EMERSON, New York, in the Chair

(Concluded from page 2029)

The Classification of Tumors for Clinical Purposes

DR. BOWMAN C. CROWELL, Chicago: The present report of the committee is labeled a progress report but the committee was appointed only in January and it has not been possible to have an assembly of the members as yet. Therefore the present report of progress must be interpreted as a report by the chairman of the committee, who has as yet received help from only a part of his committee.

Neoplasms have been classified from many standpoints; etiology, clinical features, histogenesis, embryology and gross anatomy. No terminology that can be devised in this field will meet with approval of all workers in tumors, but the committee has in mind the objective of compiling a nomenclature which will best serve to correlate for statistical purposes the known clinical facts concerning tumors. The classification should be usable by clinicians, but this statement recognizes the frequent dependence of the clinical practitioner on the pathologist. Gross anatomic features of a tumor cannot serve as the only basis for classification and yet they cannot be entirely neglected. It does not

seem possible to compile a satisfactory terminology based on any one feature of tumors, and the best that can be hoped for is one that will portray as well as possible the present known facts on the subject. It is proposed to place anew before the members of the Committee on Nomenclature of Tumors a full statement of the individual problems with which we must deal and, from the responses, compile a semifinal report for the members of the committee to consider again.

It will be necessary to enter into some of the details of the task:

1. The question has been raised as to whether the nomenclature should include in the body of the book a list of the complications that arise from neoplasms. It is proposed that the principal of these complications should be listed under 800 "Structural or Functional Changes Due to Neoplasm" and should not appear except by number in the body of the book. They should appear in the index.

2. To cover rare tumors in unusual locations it is suggested that only the more common tumors be listed in the body of the

book under the individual organ and that for the rarer tumors the list from the revised etiologic classification be recommended.

3. Numerous examples of the listing of mixed neoplasms occur in the present edition. Most so-called mixed tumors are not mixed tumors in the sense that they are of teratomatous origin. This applies particularly to those tumors which may contain cartilage or bone, or a fibroma containing fat. All such tumors should be deleted. The teratomas should be retained and perhaps the term "mixed tumors" in the case of the salivary glands when the name has a clinical connotation of some importance.

4. Shall four digits sometimes be used to indicate a modification of a particular variety of tumor? For example, pigmented basal cell carcinoma of the skin. The majority of the committee believes that three digits can sufficiently describe a tumor. Such a recommendation recognizes the desirability of three digits for the use of those who employ the punch card system of tabulation and also the fact that individuals engaged in special research can amplify the system to meet their own needs.

5. Suggestions for changes have been made in the case of tumors of the nervous system. For example, it has been suggested changing capillary fibro-epithelioma to craniopharyngioma. There is considerable objection to giving topographic names to tumors.

6. The committee has been asked to consider the use of the term "syncytial endometritis." I mention this because it involves certain policies. Such a condition is inflammatory, but a true tumor in the form of syncytioma may arise. This tumor should be recognized under 798-889. If it is purely inflammatory it may appear as 794-614 Retention of Placental Fragment.

7. The term "transitional cell carcinoma" appears in the body of the book in previous editions. If this term is to be retained, it should be applied only to tumors arising in areas where transitional cells normally occur, which is not the case at the present time. Many, if not the majority, of the so-called transitional carcinomas are modified squamous cell tumors and should be so listed.

8. In reference to the subject of pigmented tumors it will be profitable to avoid discussion of histogenesis and be content with the term "malignant melanoma," which cannot be a subject of controversy.

9. There is some lack of consistency in the present edition in dealing with neoplasms arising from the fetal anlage. It is proposed that the list under section C on page 87 be enlarged to include the known instances of this entity. They could well be placed under 87x.

10. It has been interesting to note the unanimity of members of the committee to the suggestion that the term "hypernephroma" be deleted. It has served as a cloak for much ignorance. When these tumors arise in the kidneys they should be classified as carcinoma of the kidney and, when in the adrenal, they should be classified as adenomas or adenocarcinomas of the adrenal cortex.

11. Glomus tumors should be recognized and given an appropriate place in the etiologic classification. Any alleged relation of this tumor to Schimmelbusch's disease should be completely ignored.

12. It has been suggested that adenocarcinoid of stomach and intestine should be recognized. A final recommendation as to the disposition of this entity is reserved for the future.

13. Endothelioma is a term which has served as a catchall for many tumors the nature of which could not be accurately determined. A recommendation will be made later, but the term should be retained in the etiologic classification and referred to under a certain group of organs.

14. With regard to muscle tumors several members of the committee feel that introduction of the term "myoblastoma" would be confusing and is a reversion to the time when every mesodermal tumor was supposed to have arisen from a specific cell. Most of these tumors are leiomyomas. The fibrous element in them is apparently not neoplastic. We suggest the retention of the term "myoma" with the subheadings of leiomyoma and rhabdomyoma when their origin from smooth or striated muscle can be determined.

The personnel of the committee is Dr. A. C. Broders, Rochester, Minn.; Dr. C. L. Connor, San Francisco; Dr. Max Cutler,

Chicago; Dr. C. F. Geschickter, Baltimore; Dr. Ralph E. Kendall, Hartford, Conn.; Dr. L. A. Pomeroy, Cleveland; Dr. Mont Reid, Cincinnati; Dr. Walter Schiller, Chicago; Dr. Shields Warren, Boston; Dr. John E. Wirth, Baltimore, and Dr. Bowman C. Crowell, Chicago, chairman.

DISCUSSION

CHAIRMAN EMERSON: Is this, in the main, the way you wish to have the revision undertaken, by specialist committees nationally representative, to take up each of the moot problems within individual specialties? This is a sample of the kind of thing that is in process and that must be done over the ensuing months.

DR. GEORGE BAEHR, New York: The plan for this Committee on Tumors and for other committees seems perfectly feasible. It would seem wise to have representation of national organizations designated to work with the committee. Although the national society should be sufficiently represented, there should be some authority given to the special committee to make recommendations to the central group that assists in the final preparation of the revised edition.

DR. MORRIS FISHBEIN, Chicago: From the point of view of getting the job done, and getting it done with the utmost usefulness at the end, there are two points that should be kept in mind: First, that it is hard to get people to do this kind of work. People here represent an especially interested group, but the number of men sufficiently interested to give largely of their time and of their effort is not so great as to provide a wide latitude of choice. I agree with the suggestion of Dr. Baehr that it will not be possible to organize committees on a strictly representative basis, including all national organizations, and then to expect appointees from those committees to carry back the discussions to the organizations. That method would carry on the work interminably and we would never get anything done. The second point is that it is of the utmost importance that we approach this with the philosophy again in mind that we are not going to make all the changes that we could make. We know that medicine advances rather rapidly and that specialists frequently have concepts regarding the uses of such material which are far beyond the practical application of those concepts by the vast majority of hospital record librarians and clinicians in hospitals that will use the Standard Nomenclature. It is quite possible to take up any one of these classifications and make innumerable changes, just because a change is possible. On the other hand, as Mrs. Walker pointed out, it is rather important not to change too rapidly, not to change before it is certain that the change is one which will stand, so that one will not have to be constantly shifting the code numbers and the use of the book.

AFTERNOON SESSION

CHAIRMAN EMERSON: The four departments of the government have not found it practicable to use the Standard Nomenclature. We know the difficulties and limitations of material they handle in their respective institutions, but an important gesture that we should look forward to is an agreement among the federal departments either to accept or to improve what is acceptable generally to the institutions for the sick elsewhere in the country. Each one of these departments deals with the other department's patients at one time or another, and the interchange of cards and records causes duplication and confusion which might be avoided if this Standard Nomenclature were used by all the federal departments. I hope the representatives of the four federal departments here will see if they can't come to an agreement, so we can deal with them as a unit instead of four different hierarchies of medical practice.

Progress Report on Revision of the Standard Classified Nomenclature of Disease

DR. EDWIN P. JORDAN, Chicago: We have received in this office a large number of letters from record librarians, physicians, and hospitals and other groups calling attention to specific omissions or mistakes in the Standard Nomenclature, criticizing the Standard Nomenclature in certain respects and making suggestions. For the most part the suggestions have been divided much as the book has been divided, into the special sections in which they properly belong. Some of them are matters of general editorial policy. The mechanism of action has been to

place these suggestions in the hands of individuals who had previously been interested in the Nomenclature, or other individuals or delegates of special societies who were especially interested in classification in their respective fields. After referral, we received comments as to whether changes should be made, additions made, or deletions. There has been much more pressure for additions than there has been for deletions. At present this revision is far advanced. Practically every section has already been subjected to careful examination both in this office and by specialists, and most of the proposed additions have been either rejected or accepted. There have been changes made where indicated, and a few deletions. We should at this time recommend some mechanism for approving or disapproving the specific sections of the Nomenclature. The revision of each section but two has been practically completed, so that we have made the changes on the particular pages to which they apply.

It is believed that there are many places in the Nomenclature which can be simplified and that some of the requests for additions should be resisted, but that nevertheless the Nomenclature can be complete from the standpoint of classification. An important question is How often will it be necessary to revise the Standard Nomenclature? What is the feeling of the conference? Related to this is the question whether it would be possible to develop supplements to go out to the purchasers of the Standard Nomenclature at intervals of an unspecified number of years rather than such frequent complete revisions of the Standard Nomenclature.

The whole question of the formation and mechanism of action of special committees might be discussed at the same time. It is almost certainly advisable that there be some kind of permanent editorial committee to discuss or to consider questions of editorial policy arising in the intervals between the national conferences on medical nomenclature. Other committees are probably indicated. The approval of the work of the special committees or special sections of the Nomenclature is rather important. Is it going to be necessary to require or to obtain the approval of national specialists' societies on particular sections of the book? The mechanism of doing so would be awkward. There is a delay between the time when revision is complete and the time when it would come before an annual meeting of a large specialist society. The formal action of the society would ordinarily add little to the book itself, since work of this kind is generally done by one or two individuals in each specialty, anyway.

DISCUSSION

DR. THOMAS R. PONTON, Chicago: I think the Nomenclature should be revised at least every three years. There is a constant change in the terminology of medicine, and if we are going to keep up to date we must make provision for revision. I see no reason why we should not adopt a loose-leaf system of publication. The idea of a pamphlet revision is impracticable. With the Alphabetical Nomenclature, at one time revision became necessary after publication of our first bound volume. We did not want to put the people in the hospitals to the expense of buying an entirely new Nomenclature, so we published a pamphlet revision. We even went to the trouble of publishing that on a paper that could be cut and the revisions pasted in as marginal notes on the original edition. In my visits around hospitals I never saw one of those used. That revision was not worth the time and expense of getting it out. The loose-leaf, however, I believe practical. We can then, at intervals of three years, publish supplementary pages which will replace those already done. In that way, without the hospitals going to the expense of buying an entirely new volume, they will be up to date. It is surprising to find hospitals today using some of the old nomenclatures. I ran across a copy of my original Nomenclature published in 1927, in visiting a hospital two years ago. The statement was made that they didn't feel justified in buying a new Nomenclature to put on the several floors of the hospital. That is the reason I believe in the loose-leaf idea.

DR. GEORGE BAEHR, New York: The question of a loose-leaf volume was considered when the previous editions were published. A preliminary trial printing of a Nomenclature was made in 1932, and after about a year when many of the omissions were picked up the first official edition appeared, in 1933.

However, after hospitals began to use it a great many more omissions and inaccuracies were discovered, and it became necessary to publish the second—this is the last edition—in January 1935. So it is now more than five years since this edition was printed. From the fact that our attention is being called to fewer serious omissions, we can safely put off publication of the new edition for probably ten years, provided, the new information that may arise, or new designations in disease that may be decided on, be called to the attention of hospitals that have subscribed, in some way, either by a supplementary pamphlet issued every few years or by some letter form that can be used in the record room and in the wards for making proper corrections in the book. I am in favor of a ten year revision, with supplementary information distributed when necessary during the ten year period.

DR. MORRIS FISHBEIN, Chicago: We in the Association office will be largely responsible for the entire printing task and the upkeep and maintenance of the organization necessary to carry this work out. The matter of a loose-leaf system is almost out of the question because of the difficulty of developing such a work, the increased cost and the cost of maintenance. While hospitals might object to buying a new edition, the initial cost and maintenance on loose-leaf is considerably greater than the publication of a single volume. The frequency of revisions must be intimately bound by the mechanism by which the revision is to be brought about. We should first address ourselves to the question as to who is to undertake the primary responsibility for the publication. One of the first steps is to select some one who will act as chief editor of the publication and carry the final responsibility. The Board of Trustees of the Association, at the suggestion of the General Manager and the Editor, has selected Dr. Jordan to take that responsibility. The next question relates to making the final decisions in each field. Obviously we must have committees. These committees cannot meet every month or even every year to go over the entire question of changes in nomenclature and will have to consider by correspondence the suggestions that are made. Then, as each member gives his opinion, it will probably be up to the chairman of the committee to make the final decision as to the necessary revisions, based, of course, on the information sent to him by the members of his committee as to what changes are to be made. His committee, having made that decision, will forward its corrections to Dr. Jordan, who would then arrange for proper incorporation of those suggestions into the volume. Should he find it undesirable to incorporate the changes voted by that committee, he would have to refer the matter back to the committee for further consideration. It is the desire of the American Medical Association to have this Nomenclature a cooperative effort in which all the learned societies and all those having responsibility in this field will indulge, and that means there must be conferences. The Board of Trustees decided that a conference about every five years, of this type, would serve to crystallize the points of view of those most interested. In other words, each five years a conference of this type might be held, the opinions that had developed in the meantime crystallized, committees to carry on the work until the next conference established, and a revision of the book brought out. That would not necessarily mean that each hospital would have to buy all new books every five years. It should be possible to develop in small pamphlet form the essential changes, so that those hospitals which did not care to invest in a new volume could buy the pamphlet containing the fundamental changes that had been made in the five year period. That is a compromise between the issuing of annual or monthly, semiannual or biennial supplements and the loose-leaf system. I am trying to be practical in keeping the cost of the work down to a minimum in order to get the widest possible use. If we would adopt a procedure whereby we would issue the book at about five year intervals we could keep it at the present relatively low cost. Then the hospitals could decide at each five year period whether or not to invest in a new edition or to invest in a book of revisions, for which the record librarian would have the responsibility.

CHAIRMAN EMERSON: The policy which we found indispensable in the years we were carrying it on in New York was that there had to be an executive committee of the National Conference that met several times a year to confer with the editor on

matters of general policies which were presented to us by the conflicting interests of the specialty groups we had asked to advise us. We may find a similar method desirable in addition to the special subcommittees. The specialist subcommittees should have indigenous authority, as it were, to express preference for or against inclusions of changes.

DR. MONTAGUE L. BOYD, Atlanta, Ga.: Is it essential that a definite time be set for revision?

CHAIRMAN EMERSON: Every ten years we must look forward to the decennial revision of the International List of Causes of Death. That is a thing fixed, after sixty years of practice among the nations. We are dealing with matters that change much more quickly and that are subject to clinical fashions and the influence of university teachers and hospital leaders. If we could commit ourselves now to an edition in 1945, the one that comes out in 1950 will be the one that will immediately follow or be almost coincident with the international revision of that year, which will, in fact, take place in the year 1948.

DR. BOWMAN C. CROWELL, Chicago: I would like to move that this conference go on record as recommending to the American Medical Association a consideration of a quinquennial revision of the work.

DR. EDWIN P. JORDAN, Chicago: Before passing the motion I would like to hear from the record librarians.

MRS. STELLA FORD WALKER, Chicago: The record librarians are not the ones to fix a policy of that sort. I have used the Standard Nomenclature only three years and I have had few requests in that time for questions of extension of the code that we couldn't take care of without upsetting any of the other questions. There have been occasions when the specialties have wanted additional items in their sections, but we found ways to take care of it. A five year revision is all right, as far as my experience goes.

MISS DOROTHY L. KURTZ, New York: A five year revision would be what I would suggest, from a record room standpoint.

MISS LILLIAN H. ERICKSON, Chicago (American Association of Medical Record Librarians): I think the five year period would take care of the medical record librarians. The record librarians would be happy to be represented on the Advisory Board and possibly bring forward some of their problems, as far as usage of the Standard Nomenclature is concerned.

DR. NEIL A. DAYTON, Boston: We already had the old classification on our statistical cards in 1933, and we had to change over to the new nomenclature at that time. It cost us in our department about \$600 to change over the cards for our resident population. If that were happening any oftener than every five years, it would be quite a little expense. I think five years is the ideal period.

COL. CHARLES G. SOUDER, Washington, D. C. (United States Army): Our nomenclature in the Army, which is quite a restricted one, has not been materially revised since 1917. If you want to use statistical material for purposes of comparison, I should think the more stable the Nomenclature could be and the less frequently revised, the better it would be. I would suggest a revision coincident with that of the International List of Causes of Death, not oftener than every ten years. There will be, of course, a great many changes, but will it not be true that those will be changes in diseases of infrequent occurrence, so that the necessity for any elaborate change should not be great? Medical knowledge is not going to increase at that rate. Medical fads and fashions will change, but I don't think they should be given undue attention.

CHAIRMAN EMERSON: Isn't it true that the list used in the Army is much more restricted in number, and isn't it inevitable that a list that decides to restrict itself in the beginning is likely to have less demand for change than one which is as comprehensive as the one we have attempted?

COLONEL SOUDER: Our list of diagnostic terms is limited to 1,000. If the physician wants to call tonsillitis something else, we tell him he can't do it.

CHAIRMAN EMERSON: And the Public Health Service Nomenclature is 10,000.

CAPT. WILLIAM E. EATON, Washington, D. C. (United States Navy): The current Nomenclature of the Navy, which was just

issued in our new manual for 1939, contains 2,715 diagnoses, which are classified under various groupings, there being twenty-seven classes. This has about the same categories as the Army list. We take into the hospital the Navy and Marine Corps men, the Army men from Fort Sheridan and, when necessary, elsewhere, the Civilian Conservation Corps men up to the number of sixty, the WPA workers and some veterans. Our diagnoses are satisfactory to all these agencies. We have the Veterans Bureau list which we use also. The Navy is a highly specialized service. We find conditions that may not occur in civil practice. We have to fit the diagnosis to the condition. From time to time we find additional diagnoses which we have to put in to have something to use in connection with some of the features of naval affairs. I have tabulated things under injuries and under the various causes of violence. In aeronautics we have collisions in full flight with other aircraft, collisions in full flight with objects other than aircraft—such as running into a boat on the water. We have to conform to this restricted list. Reports go into the bureau and are put on the tabulating machines. We can tabulate diagnoses and obtain statistical data by just asking at the door of the room where it is done. We have a stated number of operations which take up about four pages of our pamphlet, in English, in Latin and in anglicized Latin, which fulfil our needs. If any interested individual would show the Surgeon General of the Navy a need to add to or change, I think it could be done with cooperation.

DR. HOWARD FOX, New York: There are two questions: first, what we want, and, second, will the American Medical Association finance a revision every five years? I think five years is an ideal time for such an extensive book.

CHAIRMAN EMERSON: It is curious that a man in the Army can have only 1,000 sicknesses, and when he is in the Veterans Bureau he can have 15,000, and when he comes into the clinical care of clinicians in civil practice 1,000 isn't nearly enough to specify the kinds of things he can have. It isn't a question of recommending to the Navy that they have the same number of diagnoses that we have, but to suggest the desirability in comparability of professional accuracy and completeness of description of both etiology and location. Those are things which we believe the federal medical services might with advantage study, to see how nearly they can come up to the degree of precision and completeness which has been found desirable in systems with a great many more hospital beds, even, than those that are represented in the federal service. The motion is that there should be a revision every five years and that we ask the American Medical Association to commit itself, so far as possible, to that policy. Those in favor of this policy please say "aye"; opposed, "no." I hear no "noes," and the resolution is passed. The other matter is, Shall we suggest the creation, under the editorial policy of the American Medical Association, of a general advisory committee on editorial policy to act, as it were, as an executive committee in the interval between the quinquennial conferences?

DR. FISHBEIN: If this conference were to recommend to the Board of Trustees of the Association a suggested editorial board the Board of Trustees would probably accept the suggestion. I move that there be developed an advisory editorial board of six to cooperate with Dr. Jordan, as managing editor of this publication, with a view to serving during this next five year period as an advisory editorial board for the publication of the Standard Nomenclature, and that it be left to the chairman of the conference, with the executive committee that was established in the original conference, to nominate to the Board of Trustees of the Association the members of the advisory board of six.

[The motion was seconded and carried.]

CHAIRMAN EMERSON: The appointment of the subcommittees was proposed in the same manner, or would those subcommittees be appointed by the editorial committee?

DR. FISHBEIN: That is for the conference to decide.

CHAIRMAN EMERSON: We should leave the appointment of the special subcommittees, as may be needed, to the editorial committee.

DR. DUNN: Since I have been in this conference I have heard of at least two lists I didn't know about, one of diseases and one of operations. I think Dr. Jordan would do a good service if

ORGANIZATION SECTION

he could list the terminologies that are being used so that all of us could write and get them and see what they are.

DR. BAEHR: Miss Kurtz has made a suggestion concerning necessary abbreviation of the Standard Nomenclature which must be taken seriously because of her large experience and her deep interest in this subject. However, what abbreviations are made cannot do violence to the basic plan or require any radical changes in the record room filing. Otherwise, in attempting to solve the criticisms and objections of one group, one will lay oneself open to a tremendous wave of criticism from all the hospitals that will be inconvenienced. However, the volume can be reduced in size. Also in some parts of the book some of the headings can be put in boldface type and can be employed by some of the special services which do not want to keep a record of the refinements in the categories under the main headings. I refer, for example, to a condition like obesity, which diagnosis will be adequate for a surgeon but might not be adequate for an internist, who might want to group his cases of obesity as due to overeating, to hypothyroidism and to other causes. Similarly, under tetany somebody might be quite satisfied to put down the term "tetany" and let it go at that. It isn't a complete diagnosis, but no one can force a clinician or a specialist to go into refinements of diagnosis if he is incapable of doing it or if he doesn't want to do it. However, under tetany one will find that there are six or seven types and different types of mechanism, and for those who wish to record the different varieties the volume should permit that and yet, at the same time, allow flexibility. I think that this can be accomplished without doing any violence to the basic philosophy underlying the work.

MISS KURTZ: The main point I wanted to bring out this morning has been rather obscured by what was merely a suggestion. The abbreviated list was the suggestion, and not the main point. What we wanted to make sure this conference would consider was the difficulty that one group of specialists found in dealing with terms that belonged to another group. We wanted to make sure that some provision was made by this conference to look into that matter, and not merely treat it, as has rather been the habit heretofore, as just a lazy man's excuse. We think it has got beyond that point.

DR. WARREN P. MORRILL, Chicago (American Hospital Association): If Columbia-Presbyterian, with its staff, finds difficulty, how much is it multiplied in the general run of non-teaching hospitals? I suggest that there be in the actual format this distinction between obligatory and voluntary terminology; that is, "obesity," which may be sufficient, would be an obligatory term perhaps printed in boldface type, with the subdivisions under it. The seven migraines could be left for those who are interested in the distinction between the seven different migraines, while the average man would be obliged to go as far as saying "migraine" but no further.

CHAIRMAN EMERSON: I must reinforce, as a member of the faculty of P. and S. the insistence of my colleagues that we make some move which will permit either a distinction between obligatory and facultative, so that people who wish a simple obligatory scheme of terms can use it without damaging the complete list, which we hope always to have published in toto. There doesn't seem to be any technical reason why that can't be done, and when the committee is ready to consider it I shall be glad to submit from technicians with whom I have been in conference a possible mechanism by which this can be done.

DR. FISHEIN: It would be possible, after we have had some experience getting out this new revision, to prepare as a simple pamphlet a list of the main headings and subheadings with the numbers, for the use of those smaller institutions which cannot go much beyond that, but such an activity is directly opposed to progress in educating physicians to endeavor to make really descriptive, scientific diagnoses. I think the general effect for the advancement of medicine is vastly improved by endeavoring to hold to the list as now constituted and not to offer a short-cut simply because that is cheaper and easier.

DR. BURRILL B. CROHN, New York: The diseases of the alimentary tract constitute sixty-nine pages of this book, or practically 15 to 16 per cent of all the terms. Although I sat with the original committee, I am rather annoyed to see how often the same term springs up: achlorhydria, achylia gastrica, hypo-

chlorhydria and acidity, as well as paralytic ileus, and any other number of names. I think, that with authority, I could cut down this one section alone and condense the whole thing into sensible terms and cut the expense of the publication, but I do not think revision of the book should go longer than five years. Five years ago there was no flexible gastroscop used in this country. Today there is a huge terminology and literature growing up on the subject of gastritis, for which there is no provision in the book. If you wait ten years, the subject would probably be obsolete and completely changed before one had a chance to present it. I favor this movement to cut down the size of the book, to simplify the items and stop the duplication of terms. As far as any specialty is concerned, we have no trouble at all with the national society. I have full authority to act or make changes such as I have wished to. I have submitted my report to them. I think a simple committee, working with the approval of the national society, would be a perfect mechanism for the revision of the book.

CHAIRMAN EMERSON: The idea has been suggested that while we continue in the book all legitimate subdivisions of site and etiology which add to the precision and completeness of diagnoses, we make it possible, by some particular selection of printing or order or line of the presentation, to use the frequently employed diagnoses without any necessity in all instances of using the ultimate refinement. If a hospital wants to limit to a certain number instead of going to an ultimate subdivision, it should have the privilege of doing it, but it should deny a methodical way. We have received practically a self-denying statement from the gastro-enterologist. We may find other specialties will be willing to limit the number of diseases which they recommend that can really be accurately distinguished one from another. That is the first kind of concentration or elimination. It has been suggested that this matter be referred to the editorial advisory committee. Unless I hear objection, I will consider that this matter of abbreviating or abridging or concentrating the list, in any way consistent with keeping the present plan of thoroughness, shall be referred to the editorial advisory committee.

[The motion was carried.]

DR. JORDAN: We have been subjected to many letters and pressures of various sorts to add to the Standard Classified Nomenclature of Disease special diagnostic categories for the classification of dental diseases, pathologic specimens, x-rays, electrocardiograms and others. I feel that this should not be done, that it does not come within the scope of the Standard Nomenclature to include such things, and that there would be no limit to what we would be supposed to add under those circumstances. There are some eight or ten suspected diagnoses in the Standard Nomenclature now. I believe they should be removed. I don't believe the Standard Nomenclature should differentiate between a diagnosis and a suspected diagnosis. If any one wishes to indicate that something is suspected, he can add a Y at the end of the classification. Dr. Baehr referred to one method of simplification which seems practicable and will materially decrease the size of the book. That is the question of listing, as a general diagnosis, certain disorders which may appear in almost every region or organ. An abscess, for example, may appear almost anywhere, and rather than listing it under each organ in which it might appear, I believe we can have a general diagnosis of abscess, with permission given to the physician or the record librarian to fill in the location from the topographic numbers in the book. That would apply to such conditions as abscess, endometriosis, leukoplakia, anthrax, filariasis and many others. They might also be listed and should be listed under the sites where they appear most commonly. Dr. Crowell mentioned the question regarding the listing of complications of neoplasms. We have in the book a number of complications: "perforation of the stomach due to contiguous neoplasm"; "hemorrhage of intestine due to contiguous neoplasm"; "hemorrhage of intestine due to contiguous neoplasm." I believe they should all be entirely removed from the book. The disease is the neoplasm; the rest is a complication. We must realize that some things have to be left to the patient's chart itself. Not every detail of a clinical examination can be placed in the diagnosis. The editorial matter which I wish to bring to your attention is with regard to the use of eight and nine digit diagnoses. It is possible to place such lengthy diag-

noses on punch cards and the question has arisen as to the possibility of making all the diagnoses in the book ten digit diagnoses. On the whole, I think it would be advisable to keep the number of digits as few as possible, but we have received many letters on that subject.

MR. RICHARD H. DYER, Washington, D. C. (International Business Machines Corporation): I was invited to this conference as a representative of a tabulating machine corporation, but I speak in the interest of Dr. Bullock of the Los Angeles County Hospital. The subject he brings up is this, that the number of positions in the morbidity code should be, if possible, reduced to the smallest number. If you will look at the code Mrs. Walker has, you will notice that it has twelve possible positions, and that would indicate, on the basis of the decimal system, that there would be one trillion possible types of morbidity. Using that as a possible index, conceivably there could be some reduction in the number of digits which are used to express any type of morbidity. Another point Dr. Bullock would like to make is this: Since there are probably not one trillion types of morbidity, it might be possible to go to a ten digit code. In other words, our dollars and cents are expressed in ten digits, from 0 to 9. The Logie code is expressed in twelve positions at this time, X and Y. Since scientific agencies throughout the world are using the ten digit system, wouldn't it be possible to revise the code and put it on a decimal basis rather than use a duodecimal or twelve position code? That would simplify mechanical tabulation and make possible certain correlations which are not practical on a machine basis now. Dr. Bullock would also like to see the code established as a fixed unit. In other words, instead of having 3 and decimals added up to a total of six positions, would it be possible to reduce that to five and have it expressed as a five digit code in the Nomenclature opposite the type of morbidity? As a representative of a company in the tabulating machine business, I wish to say that our engineering forces are at work developing equipment which will handle all these problems which hospitals have in connection with their morbidity tabulations.

DR. DUNN: Wouldn't it be advisable to take all the record librarians who are in hospitals that have been actually using this code and solicit from them a complete description of what difficulties they have had in adapting it, the feelings of their staff, and all of the suggestions that must have been cleared largely through them? That would get the practical problems which have been coming up here before the committee.

DR. JORDAN: We have had requests to include in the Standard Nomenclature dental terminologies, terminologies for the classification of pathologic specimens, electrocardiograms and x-rays.

DR. FOX: I move that the requests be disapproved.

DR. FISHBEIN: On the ground that it is not feasible, with the present setup, to take up such extra sections as are requested. It is not expedient at the present time to undertake them.

Problems of Terminology in the Field of Physical Medicine

DR. FRANK H. KRUSEN, Rochester, Minn.: I appear as a representative of the Council on Physical Therapy and as chairman of its Committee on Nomenclature. We are interested not in statistics but in preparing a workable classification of therapeutic procedures in the field of physical medicine. Our problem is to obtain a list of definitions. We have tried getting the written opinions of a large group of specialists, selected because of their locations in leading hospitals and institutions. The plan was not particularly satisfactory. We then thought that probably it would be better to pick out a small committee, with a skilled physicist, because our problem is physical medicine, a skilled lexicographer, and a specialist in the field to work out a set of definitions.

We are confused by such problems as terminology for a procedure such as that in which an electrical constant current is used to introduce the ions of certain drugs into the superficial tissues. For years, physicians have called this procedure "ionization," which is incorrect. Then some purist suggested the term "iontophoresis." That didn't seem satisfactory, and somebody said the term should be "electrophoresis." Now physicists say that we should call this procedure "common ion transfer."

We have the problem of trade names: hypothermy, from a trade device "Hypotherm"; inductothermy, from a trade name "Inductotherm"; endothermy, from a trade name "Endotherm." Shall they be included in a list of definitions or shall they be excluded?

To the uninitiated observer, this conference seems to have been confusing two closely related problems, nomenclature and statistics; terminology, per se, and grouping of terms; if those two could be separated, confusion could be avoided.

Our committee is trying to prepare for clinical purposes an acceptable list of definitions in the field of physical medicine.

DISCUSSION

CHAIRMAN EMERSON: Dr. Krusen gave a list of different terms that stem entirely from therapy, and we can no more list therapeutic procedures in this field or drugs than we could in any other special field of application, but so far as your request concerns diagnostic definition we ought to be able to meet your needs.

DR. FRANK H. KRUSEN, Rochester, Minn.: We are not asking that a list of definitions be incorporated into the Standard Nomenclature. We are merely preparing, as part of our Council's work, a revision of a list already published by that Council. We ask only that this be considered by those of the conference who have experience in this particular field of nomenclature. We are interested in nomenclature, not in statistics, as far as this particular committee is concerned. We are merely asking for advice.

Nomenclature and Classification of Allergic Disorders

DR. SAMUEL M. FEINBERG, Chicago: The difficulties in attempts to delineate and classify disease conditions and scientific terms arise from several sources: 1. The long-continued usage of terms, usually of lay variety, has given an almost indelible stamp to some diseases, even though the appellations create entirely erroneous impressions of the nature of the conditions. 2. The tendency to combine stems from words in Greek and Latin to produce combinations has resulted in hybrid products which are neither scientific nor clear. Anglo-Saxon and Arabic origins also have complicated our etymology. 3. The honor reflected from scientific discoveries has given rise to eponyms, which are neither scientific nor descriptive. 4. Changing concepts of the nature of pathologic conditions result in changing and multiple terms.

I will attempt to throw light on the classification and terminology of the clinical manifestations of allergy. It would be well to define briefly the most important fundamental types of hypersensitiveness. Hypersensitiveness is an increased reactivity to a specific substance which, in normal subjects, produces little or no reaction. Allergy is the usually accepted term for all types of human hypersensitiveness. It may be subdivided into several components. Atopy is a type of hypersensitiveness peculiar to man, subject to hereditary influence, presenting the characteristic specific immediate whealing type of reaction, having the circulating antibody reagin and manifesting certain peculiar clinical syndromes such as asthma and hay fever. Bacterial allergy (tuberculin type) is not subject to hereditary influence, is normally dependent on previous infection to the specific organism, is characterized by the delayed type of infiltrative reaction and does not have any demonstrable circulating antibodies. Contact allergy is a type of hypersensitiveness almost exclusively confined to the epidermis, caused usually by a nonprotein allergen, giving no positive whealing type of reaction but rather a delayed eczematous reaction to prolonged contact with the allergen, and displaying no circulating antibodies. Just because a certain manifestation (asthma, for example) is classed as an allergic disease does not necessarily imply that the inference is made that allergy is the sole cause for every instance of such affliction. The word asthma originates from the Greek, meaning "panting." The majority of authors employ the term "bronchial asthma" to denote the common atopic variety, such as asthma to pollen, foods or animal danders. They differentiate bronchial asthma from asthma due to left ventricular failure (cardiac asthma) and from asthma due to bronchitis. The cardiac asthma is identical in mechanism to the atopic variety.

being spasmodic, presenting the same pathologic and physiologic manifestations in the bronchi and relieved by the same drugs, such as epinephrine. Hence cardiac asthma is bronchial asthma. It is confusing, therefore, to use the term bronchial asthma as it is commonly used. It is proposed that the general term asthma be employed for all such types of spasmodic breathing. If the specific allergic etiologic factor has been located, the condition should be designated allergic asthma.

What shall we name the syndrome of watery rhinorrhea, sneezing and spasmodic blocking? Shall it be hay fever, allergic rhinitis, vasomotor rhinitis, perennial rhinitis, rhinitis vasomotoria, hyperesthetic rhinitis or intumescent rhinitis? Shall we then call this affliction "allergic rhinitis"? Authors of textbooks on allergy have arbitrarily regarded this designation suitable. However, in the present state of knowledge we have no right to assume that other than allergic causes are not instrumental in producing these symptoms. Vasomotor rhinitis is not a good name because it has the same inherent inconsistencies as the term "bronchial asthma." Hyperesthetic rhinitis, we believe, is the most suitable term for this condition, since it describes the essential features of the disease, the sensibility to stimuli. If the nasal symptoms are due to allergic causes then the designation allergic rhinitis is justifiable. Of the latter the most common varieties are the seasonal and the nonseasonal. "Hay fever" has been the most common designation for the seasonal form. This term is a misnomer. The disease is not due to hay nor is it accompanied by fever. It were better to refer to this condition in general as seasonal rhinitis or seasonal allergic rhinitis. If the symptoms are due to pollen, then we may refer to it as pollen rhinitis or pollinosis. The nonseasonal form may be designated as perennial allergic rhinitis.

CUTANEOUS MANIFESTATIONS

Urticaria is an old established appellation. The origin of the term is derived from the genus of plant *Urtica*, which has the general property of producing itching swellings on the skin of every one by contact with it. There is no serious objection to this term. Angioneurotic edema is interchangeable often with urticaria and not infrequently the two occur in the same individual in the same attack. Among the definitely known causes of this manifestation is allergy. The objection to the eponymic term Quincke's disease is self evident. The name angioneurotic edema is objectionable because it conveys the impression of a neurosis, which steers away from the truth and tends to deaden the stimulus for future investigation. Probably the most suitable designation would be acute circumscribed edema or perhaps giant urticaria.

Perhaps in no other phase in medical nomenclature is there as much confusion as in the field of "eczema." "Eczema" has been the waste basket of misunderstood, unidentified forms of inflammatory lesions of the skin. In allergy we are concerned principally with two types of so-called eczema. One type is definitely associated with other diseases of atopy, such as asthma and hay fever, in the individual, the family or both. This dermatosis has been called neurodermatitis, generalized neurodermite, neurodermite, flexural eczema, lichen chronicus simplex disseminatus and just eczema. All of these are objectionable on the grounds either that they stamp this dermatosis with a neurogenic character or that the name is not accurately descriptive. There can be no question now of the true atopic nature of this manifestation and since the lesions are truly of the nature of a dermatitis we may as well combine the two ideas and agree with Sulzberger that the most fitting designation for it is atopic dermatitis. The second important variety of allergic dermatitis is one in which the allergy is apparently confined to the epidermis and the inflammation is produced by direct contact. European dermatologists have correctly referred to it for years as "eczema." The name dermatitis is permissible because an eczema is still a dermatitis. However, the contact feature should be expressed in the name, such as contact eczema or contact dermatitis.

For the one-sided familial headache which is so frequently allergic, migraine is an excellent term. Many ophthalmologists believe in the allergic nature of vernal conjunctivitis. There is sufficient evidence to indicate that some of these cases are

allergic. The term vernal catarrh, I believe, should be dropped in favor of the former name, since "catarrh" has been another pigeonhole in which an attempt is made to hide our ignorance.

Classification of Allergic Conditions

DR. J. FREDERICK PAINTON, Buffalo: Like every new conception allergy is being used as an explanation for a great variety of conditions that hitherto has been unexplained. Allergy plays an important role in many diseases but it should not be used as a scapegoat for every obscure disease process. A review of the literature during the past ten years failed to reveal any effort toward the establishment of a basic classification in allergy. In attempting to formulate any sort of recording system of allergy, we must endeavor to establish this classification on both a topographic or regional basis and an etiologic relationship. Every new fiber, every new cosmetic, every new drug is a potential cause of allergy. When we consider the numberless known allergens, it is apparent that there is no advantage in adopting individual allergens as a basis for classification. It might be practical to base this etiology on the mode of production, as by ingestion, inhalation, injection and contact. It also seems necessary to indicate whether the allergy is seasonal or whether it occurs throughout the entire year or perennially. Allergy in the nose is properly called allergic rhinitis. It would be classified under disease of the nose or nasal mucosa. The term hay fever should be abandoned. Allergists feel that the most acceptable name is pollinosis. Thus under the seasonal forms of allergic rhinitis we would place the term pollinosis. To classify pollinosis further as to the exact season is essential because some cases occur in the spring, some in the early summer and some in the fall. The perennial variety is frequently designated as hyperesthetic rhinitis, vasomotor rhinitis or perennial hay fever; obviously the latter term should be avoided. We would classify the condition as allergic rhinitis, perennial, and specify whether it is of the inhalant or ingestant type. If the allergens producing such a condition can be grouped together, such a group as animal emanations, or dust, might be used to specify more definitely if placed in parenthesis.

It might be well to follow the suggestion of Cook and Coca and classify all bronchial asthma as either allergic or non-allergic; if allergic, specify whether perennial or seasonal and then designate in the same fashion in which allergic rhinitis was handled whether it is inhalant, ingestant, injectant or contactant. It might be necessary to add a fifth designation, focal, indicating a sensitivity to bacteria or fungi. As there are other accepted causes of bronchial spasm, we are justified in designating them as nonallergic. In this category would be placed pulmonary fibrosis and pulmonary emphysema with associated bronchial spasm, cardiorenal disease, thymic enlargement and reflex bronchial spasm.

Allergic conditions of the skin constitute an extensive subject but it should be possible to handle it in the same manner as rhinitis and bronchial asthma.

Food allergy, or gastrointestinal allergy, should be placed under disease of the gastrointestinal tract, conforming to the topographic classification. As these cases are practically always the result of food or drugs ingested, they would be obviously called ingestant and better specified in parenthesis food or drugs. However, if this syndrome of gastrointestinal allergy which is usually characterized by nausea and emesis, cramps and diarrhea results from some substance injected naturally, it would be classified as injectant.

Physical allergy, such as hypersensitivity to heat and cold, affects the body as a whole topographically and it would have to be placed in that category. From the standpoint of a mode of production, it would seem logical to consider this type of allergy as contactant.

This classification has its limitations, yet I hope it will serve a useful purpose in the recording of allergic conditions.

Problems of Dermatologic Nomenclature

DR. HOWARD FOX, New York: The average physician who looks at the list of diseases of the skin in the Standard Nomenclature will think the subject of dermatology is perhaps hopeless. The list includes some diseases which are of mere

academic interest. The last mentioned are, however, important as a background for differential diagnosis.

We have long passed the stage of merely naming diseases of the skin. To listen to some discussions at our national societies, one might think the speakers were physiologists, chemists, pathologists, mycologists or even physicists.

Many of the diseases in our list were named generations ago, before pathogenic organisms were discovered. Some of these names are so universally used that it would be almost impossible to change them. Many of them are fanciful, such as psoriasis, lichen and pemphigus. It would be difficult to change names like these, and it would be unwise until we are certain of their causation.

I realize the trend toward English and away from Latin or Greek words, but I hope that in the next edition of the Classified Nomenclature we may continue to use to a large degree Latin or Greek names for diseases of the skin. One reason for doing so is long usage of these terms. A second reason is consistency. If from 80 to 90 per cent of our terms are in Latin, to be consistent all or nearly all of them should be Latinized. A more important reason is an international one. The only possible international nomenclature is one of Latin or Latinized Greek words. While English is the best modern language for international communication, it is not universally understood.

Certain anatomic terms in Latin or Greek cannot be changed. If we must gradually change our nomenclature to English, at least we should exclude names in French or other modern languages as far as possible. In our dermatologic list we still have one French term, "perleche," and one Dutch term, "veldt sore." Thus far we haven't been able to get rid of them.

I am in accord with the tendency to omit the name of the person who first described a disease. Our list now contains only three terms which are designated solely by the names of those who first described them. They are Bowen's disease, Fox-Fordyce disease and, of course, Raynaud's disease. We will welcome the deletion of the describers' names when we are able to devise satisfactory titles for the diseases in question. In a few other disorders the name of the describer is mentioned with the disease.

The dermatologists are not the only ones who have plenty of Latin terms. How would the ophthalmologists like to have English substitutes for such terms as amaurosis, amblyopia, arcus senilis, chalazion, ectropion, exophthalmos, iridocyclitis, mydriasis and ptosis? In the revision of the Classified Nomenclature I suggest deletion of the word "infectious," which is used throughout the volume. There is no such word, according to Dorland's, Webster's, the Century, Standard and Oxford dictionaries.

DISCUSSION

DR. MORRIS FISHBEIN, Chicago: A great many of the terms which Dr. Fox characterizes as Latin are now recognized as English, and no one wants to abolish those terms.

Terminology in Diseases of the Blood-Forming Organs

DR. RAPHAEL ISAACS, Ann Arbor, Mich.: In writing a review of hematology this year, every time I came across a reference in any of the articles appearing in 1939 to "leukemia" or to a lymph gland disease I jotted down the name. There are about sixty-one odd names describing leukemia. There are not that number of types of leukemia. Is this a refined classification? Why are there so many names? I tried to classify these names in some way, and the only classification I could make was to put them in alphabetical order. There seemed to be tremendous overlapping. Which shall we take, "myelogenous leukemia," "myelotic leukemia," "myeloid leukemia"? There seems to be no hope of simplifying this list. It is difficult in hematologic subjects to give a cause of the disease, so we shall have to use some expression which is arbitrary. In this field it would be satisfactory to have in the index all these names with the proper number after them. I think many people would prefer to look in the index under their favorite name and find the classification number right there. It would solve their problems.

Sometimes a stage in a disease is given a name, like "myeloblastic leukemia," which is just a stage probably in the ordinary development of leukemia. Some of the names are clinical, such

as "malignant lymphoma"—"lymphoma" because somebody saw a lump in the body where a lymph gland would be, and "malignant" because he couldn't cure it. Some names are pathologic, such as "round cell sarcoma." There is a whole list of names which are the result of looking at a section under the microscope. Are we not to name a disease until we have done a biopsy or until after an autopsy? We must have some name during life. That is one reason for so many names.

Some of these names change so rapidly that it is impossible to keep up with the literature on the subject. Almost every few days an article comes out with a new name of a variation of some old disease. There is often confusion between groups and single diseases or specific diseases. For example, the term "lymphosarcoma" is sometimes used for a whole group of diseases and sometimes for a specific disease. There is confusion with the suffixes. For example "oid" in a term like "myeloid." Is it "myelogenous leukemia" or is it "myelocytic leukemia"? There is the ending "ic," the ending "osis" and the ending "oma," which are all confused.

DISCUSSION

DR. MORRIS FISHBEIN, Chicago: Medicine proceeds by epochs, the epoch of allergy and the epoch of advancement in diseases of the blood. It might be possible in many of these revisions to concentrate on these particular fields which mark an epoch of medical advancement.

Diseases of Endocrine Origin

DR. ELMER L. SEVRINGHAUS, Madison, Wis.: In line with what Dr. Fishbein has said, the past decade has witnessed the development of definitely identifiable endocrine materials. The same thing might be said for nutritional materials, especially vitamins. We have developed also new tools for measuring function so that we are able to talk in terms of etiology more specifically than ever before.

I might call attention to the type of thing we are advising. On page 84 in the book, the etiologic classification will have to be expanded by the addition of more vitamins. The numbering scheme makes that possible. How long the numbering scheme will be adequate, I do not know. My associate Dr. Gordon says there are now probably something like thirty-one or thirty-two identifiable vitamins. They haven't all had their clinical syndromes described yet.

In the case of the endocrine materials, the number scheme is already sadly taxed, however, because here we must plan for overactivity and underactivity in the case of each gland. There is no hope at this time of trying to assign a different number to disturbances in the growth-promoting glands, the gonadotropic, the thyroidotropic and the anterior pituitary. We shall have to list it simply as anterior pituitary and be satisfied with that. Perhaps that is just as well until we can be certain of chemically identifiable fractions of the pituitary. Even with that in mind we shall have to use every number we can find in the expansion of this scheme, and at the same time we do that we are going to suggest dropping numbers referring to function of the thymus and the pineal until somebody can define functions for those glands.

Another matter is that we should clearly distinguish between growth and development. They are at present listed as one. The number scheme will allow that to be done without much difficulty.

I invite attention to the group called "Diseases of the Psychological Unit." There is increasing need in medicine for attention to such a thing as a psychobiologic unit, but there are some reasons for thinking that infantilism and precocity and premature puberty and menopause syndrome don't belong there, since we can begin to assign them to definite etiologic forces or single organs. They are therefore recommended for deletion at that point, since they do appear again in the appropriate place with reference to a given gland.

Similar things can be said about a number of items which appear again, not under psychobiologic units, but under body as a whole. When we get to such things as obesity there is an entire section, from the bottom of page 111 to the middle of page 116. Practically that entire portion of the book we are recommending for deletion, because many of those items appear

later on and some of them will be inserted in other sections at the appropriate place. The places where they will appear will occur at two sites later in the book, one of them in the section which is now devoted to disturbances of the genital system. That is because of the rapid development of genital physiology from an endocrine point of view. Disturbances of the thymus and functional disturbances of the thyroid should all be listed

under "thyroid," instead of having "cretinism" listed in one part of the book and "hyperthyroidism" in another part. We believe we can bring together things more logically associated, which can more easily be found, and can have a teaching advantage in showing their association. In general, revision is needed also in the various types of disorders of menstrual function and fertility.

OFFICIAL NOTES

THE NEW YORK SESSION

Change in Date of Session on Anesthesia

It has been found advisable to change the Session on Anesthesia in the Section on Miscellaneous Topics from Wednesday afternoon, June 12, to Thursday afternoon, June 13. This will enable all those interested to attend the Session on Anesthesia on Thursday afternoon and the Symposium on Anoxia in the Section on Pathology and Physiology on Wednesday afternoon if they so desire.

Registration

The Bureau of Registration will be located on the second floor of the Grand Central Palace, Lexington Avenue between Forty-Sixth and Forty-Seventh streets. Fellows are urged to bring with them their 1940 Fellowship Cards, which will facilitate registration. Any Fellows who have not received cards for 1940 should secure them at once by writing to the American Medical Association, 535 North Dearborn Street, Chicago, Ill.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—The House Committee on Mines and Mining has held a hearing on S. 2420, already passed by the Senate, proposing to authorize the Secretary of the Interior to make certain inspections and investigations in coal mines for the purpose of obtaining information relating to health and safety conditions, accidents and occupational diseases therein. S. J. Res. 256, introduced by Senator Bilbo, Mississippi, has been reported favorably to the Senate by the Committee on the Library, proposing to designate a day to be observed as Doctor's Day.

Bills Introduced.—H. Res. 493, introduced by Representative Rankin, Mississippi, proposes to authorize the House Committee on World War Veterans' Legislation or any subcommittee thereof to make a comprehensive survey and inspection of soldiers' hospitals and other Veterans' Administration facilities, including any hospital with which the government has a contract for ex-service men of any war in which the United States was engaged. The committee is to be authorized to make a report of its findings to the House, accompanied by such recommendations in the form of a bill or otherwise as it may deem necessary. H. R. 9735, introduced by Representative Ramspeck, Georgia, is a bill "To encourage and promote the

highest standards of service among officers and employees of the United States by creating the Association of Government Employees." Among other things, this corporation is to be authorized to engage in educational, charitable, recreational, athletic, social, health, mutual benefits and cooperative activities, and to maintain and operate facilities incidental thereto. H. R. 9777, introduced by Representative Voorhis, California, proposes to promote national health and welfare through appropriations for hospitals and for prevention, education and control of tuberculosis. S. 3924, introduced by Senator Wagner and referred to briefly in THE JOURNAL last week, proposes to amend the Social Security Act so as to provide insurance benefits for wage earners permanently and totally disabled for causes not arising out of their employment. In addition to cash benefits to be paid, the bill proposes that the Social Security Board may make provisions for the furnishing of medical, surgical, institutional, rehabilitation or other services to individuals entitled to such cash benefits, if such services may aid in enabling such individuals to return to gainful work. The bill provides that such services shall be furnished by qualified "practitioners" and through governmental and non-governmental hospitals and other institutions qualified to furnish such services.

WOMAN'S AUXILIARY

Illinois

At a meeting of the auxiliary to the Adams County Medical Society in Quincy, Dr. Arthur Bitter spoke on "Advances in Surgical Treatment and Operations."

Members held a round table discussion on socialized medicine at the meeting of the auxiliary to the Sangamon County Medical Society in Springfield December 11.

Dr. Melvin F. Blaurock, psychiatrist at the Institute of Juvenile Research, gave an illustrated lecture on "A New Approach of the Problems of Juvenile Delinquency" at a meeting of the auxiliary to the Will-Grundy County Medical Society in Joliet.

Oregon

The auxiliary to the Benton County Medical Society is collecting books for a library for the patients in Corvallis General Hospital.

The auxiliary to the Clatsop County Medical Society has done much sewing for patients in the Doernbecher Memorial Hospital for Children in Portland.

The auxiliary to the Coos and Curry County Medical Society met in North Bend January 16. The main project of the auxiliary is helping the needy at the county farm in Coquille.

The auxiliary to the Harney County Medical Society has 100 per cent membership. *Hygieia* has been placed in all schools in the county by the auxiliary's cooperation with the Harney County Health Association.

Washington

The auxiliary to the King County Medical Society held meetings in Seattle in November, December and January. Dr. Edwin Guthrie discussed "Human Relationships"; Dr. and Mrs. Austin DeFreece, European travel; Mrs. L. S. Roach, the philanthropic fund of the auxiliary, and Senator Pearl Wamaker, the "Human Side of the Legislature."

The auxiliary to the Pierce County Medical Society was host to the auxiliary to the Washington State Medical Association at its midyear board meeting in Tacoma February 16.

The annual guest day of the auxiliary to the Spokane County Medical Society was held on January 12. A panel discussion was presented as follows: Dr. M. S. Wright, public health; Dr. C. L. Lyon, pediatrics; Drs. J. B. Plastino and T. I. Moore, socialized medicine; Mrs. I. Hanks, Spokane County Public Health Council. Dr. Moore also spoke on the platform of the American Medical Association and the Wagner Health Bill. More than 125 persons attended the meeting.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ADDITIONAL MEDICAL COLLEGE NEWS AND ARTICLES APPEAR IN THE STUDENT SECTION, PAGE 2157.

ALABAMA

Personal.—The Houston County Medical Society gave a dinner recently in honor of Dr. Mercer S. Davie, Dothan, then president of the Medical Association of the State of Alabama, and presented him with a traveling case and fitted week-end bag. Dr. Marye Y. Dabney, Birmingham, as guest speaker, discussed "The Use of Hormones in Gynecology."

Society News.—Dr. Merle E. Smith, Parrish, addressed the Walker County Medical Society, Jasper, April 12, on "Pregnancy and Cervical Carcinoma."—The Calhoun County Medical Society was addressed in Anniston recently by Dr. James S. McLester, Birmingham, on "Diet in Heart Disease" and Dr. David H. Poer, Atlanta, "The Diagnosis and Treatment of Thyroid Conditions in the Southern Area."

Postgraduate Lectures.—A series of postgraduate lectures in internal medicine opened in Montgomery, April 26, to continue for six weeks, for the benefit of physicians in Montgomery, Bullock, Autauga, Elmore and Lowndes counties. The lecturers are Drs. William A. Soderman and Julius L. Wilson, instructor in medicine and associate professor of medicine, respectively, Tulane University of Louisiana School of Medicine, New Orleans. It is also planned to give the same lectures in Dothan, Troy, Eufaula and Greenville.

CONNECTICUT

Dr. Francis Blake Made Acting Dean of Yale.—Dr. Francis G. Blake, Sterling professor of medicine, Yale University School of Medicine, New Haven, has been appointed acting dean of the school. Dr. Stanhope Bayne-Jones is retiring as dean July 1. Dr. Blake graduated at Harvard Medical School in 1913. He was a member of the staff of Peter Bent Brigham Hospital from then until 1916, when he went to the Rockefeller Institute for Medical Research for a year. From 1917 to 1919 he was associate professor of medicine at the University of Minnesota Medical School, Minneapolis. The following year he was associate in medicine at Rockefeller Hospital and from 1920 to 1921 associate member of the Rockefeller Institute; he was a member of its scientific board of directors from 1924 to 1935. He joined the Yale faculty as John Slade Ely professor of medicine in 1921 and served until 1927, when he was made Sterling professor of medicine. Among other positions Dr. Blake has been chairman of the division of medical sciences, National Research Council, 1933-1936; chairman of the Section on the Practice of Medicine, American Medical Association, 1938, and president of the American Society for Clinical Investigation and American Association of Immunologists.

GEORGIA

Personal.—Dr. Stuart P. Vandiviere has resigned as health commissioner of Americus-Sumter County to accept an assignment for duty with the U. S. Army air corps at Maxwell Field, Ala., newspapers reported. Dr. Henry T. Adkins, Cochran, has been appointed to succeed Dr. Vandiviere.

Society News.—Dr. Albert Worth Hobby presented a paper before the Fulton County Medical Society, Atlanta, April 4, entitled "Air Embolism Following Pneumothorax." Dr. Frank Lee Bivings presented a paper before the society, April 18, entitled "Relation of Asthmatic Bronchitis to Chronic Upper Respiratory Infections in Children: A Five Year Study of 235 Cases."

State Medical Election.—Dr. Allen H. Bunce, Atlanta, was chosen president-elect of the Medical Association of Georgia at its annual session in Savannah in April and Dr. Job C. Patterson, Cuthbert, was installed as president. Other officers are Drs. Julian K. Quattlebaum, Savannah, and Marion T. Benson Jr., Atlanta, vice presidents, and Dr. Edgar D. Shanks, Atlanta, secretary-treasurer. Dr. Bunce once held the office of secretary-treasurer for fifteen years. In 1941 the association will meet in Macon, May 13-16.

ILLINOIS

Society News.—Dr. Friedrich P. E. Bornstein, Rochester, among others, addressed the Sangamon County Medical Society in Springfield, May 2, on "Pharmacology of the Myocardium." Dr. Ralph H. Major, Kansas City, Mo., addressed the society, April 4, on "Therapy of Endocarditis Lenta."—Dr. Lee C. Gatewood, Chicago, discussed "Dysentery Including Amebic Dysentery" before the Madison County Medical Society in Highland, May 3.—Dr. James H. Hutton, Chicago, discussed "Recent Development in Endocrine Diagnosis and Therapy" before the Adams County Medical Society in Quincy, April 8.

Chicago

Alumni Day at University of Chicago.—Alumni of the Division of Biological Sciences, University of Chicago, will hold their annual assembly June 7. The speakers at the scientific sessions will include:

Dr. Charles B. Huggins, The Prostate Problem.
Dr. Lester R. Dragstedt, Recent Work with Lipocain.
Dr. Dwight F. Clark, Treatment of Psoriasis with Lipocain.
Dr. Keith S. Grimson, Surgical Treatment of Hypertension.
Dr. Henry T. Ricketts, Constancy of Action of Protamine Zinc Insulin.
Dr. Walter E. Hook, Studies on Hibernation.
Dr. Carl C. Pfeiffer, The Therapy of Migraine Headaches.
Dr. Curtis M. Flory, Production of Tumors by Tobacco Tars.
Dr. Francis B. Gordon, Inapparent Virus Infections in the White Rat.
Dr. Paul E. Ross, Some Impressions of Ovarian Neoplasms in Spleen Mice.
Dr. Jonathan M. Williams, Cleveland, Use of Erythroidine in Metrazol Therapy.
Dr. Abraham Kauvar, Boeck's Sarcoid (Schaumann's Disease).
Dr. V. Brown Scott, Bloomington, Ind., Observations on the External Pancreatic Secretions in the Fasting Dog.

Alumni Reunion.—Alumni of Rush Medical College will hold a reunion at the college June 6-7. The program includes symposiums on endocrines, chemotherapy, abdominal surgery, gastro-enterology, cardiovascular renal disease and traumatic surgery, and the following speakers, among others:

Dr. James W. Merriks, What About the Irritable Bladder in Women?
Dr. George E. Shambaugh Jr., Operative Restoration of Hearing in Otosclerosis.
Drs. Carl W. Apfelbach and Ernest E. Irons, Aspiration Bronchopneumonia.
Dr. John H. Olwin, Methods for Estimation of Prothrombin Levels and Administration of Vitamin K.
Dr. Evans W. Pernokis, Adequate Control of Pernicious Anemia.
Dr. Paul A. Campbell, Profound Physiologic Effects of Modern High-Speed, High-Altitude Military Flying.
Dr. Herman L. Kretschmer, Significance of Blood in the Urine.
Dr. Archibald L. Hoyne, Old and New Methods in the Treatment of Meningitis.
Dr. Herbert C. Breunhaus, The Neutralizing Capacity of Antacids.
Dr. Hillier L. Baker, Acromial and Subacromial Bursitis: Treatment by Local Infiltration and Excision.
Dr. Aaron Arkin, Primary Carcinoma of the Lung—A Prevalent Disease.
Dr. Heyworth N. Sanford, Thromboplastic Factors in Coagulation.
Dr. Clayton J. Lundy, Early Diagnosis of Coronary Sclerosis.
Dr. Clark W. Finnerud, Skin Cancer.
Dr. Adrien H. P. E. Verbrugghen, Head Injuries.

The annual banquet at the Stevens Hotel, Thursday evening, will be addressed by Dr. Morris Fishbein, Editor of THE JOURNAL. At 7 o'clock, Friday evening, a reunion of Presbyterian Hospital interns will take place in the Oceanic Room of the Knickerbocker Hotel.

INDIANA

Society News.—The Indianapolis Medical Society will be addressed, May 28, by Drs. Edwin L. Libbert, Lawrenceburg, on "Medical Application of Physical Medicine," and Edwin N. Kime, "Surgical Application of Physical Medicine." The society was addressed, May 14, by Dr. Percy S. Pelouze, Philadelphia, on gonorrhea.

Changes in Health Officers.—Dr. Walter M. McGaughey, Greencastle, has been appointed health officer of Putnam County to fill the unexpired term of Dr. William M. O'Brien, resigned. The latter's term was to have ended Dec. 31, 1941.—Dr. Claude D. Greene, Spencer, was recently named health officer of Owen County, succeeding Dr. Boaz Yocum, Coal City, who held the position for ten years.—Dr. Paul P. Bailey, Fort Wayne, has been appointed health officer of Allen County, succeeding Dr. Noah A. Rockey.

MASSACHUSETTS

Dr. Parran Lectures on the Nation's Health.—Dr. Thomas Parran, surgeon general, U. S. Public Health Service, Washington, D. C., gave the fourteenth William Thompson Sedgwick Memorial Lecture of the Massachusetts Institute of Technology, Cambridge, April 11. His subject was "Nutrition and the Nation's Health."

VOLUME 114
NUMBER 21

Society News.—The Boston Gastroenterological Society was addressed, April 3, by Drs. Charles W. Finnerty on "The Treatment of Peptic Ulcer Complicated by Diabetes Mellitus"; Timothy F. P. Lyons and Marino F. Vidoli, "Rectal Polyps: A Pathologic Discussion," and Louis F. Curran, "Achlorhydria."—Dr. Arthur M. Fishberg, New York, discussed "Essential Hypertension" before the Greater Boston Medical Society, April 2.—Dr. Moses Ralph Kaufman, Boston, addressed the New England Society of Psychiatry in Hathorne, April 24, on "Factors in Psychotherapy: A Psychoanalytic Evaluation."—Dr. Hamilton Montgomery, Rochester, Minn., discussed "Pathologic Features of Some of the Non-Neoplastic Dermatoses" before the New England Pathological Society in Boston, April 18.

MICHIGAN

Personal.—Dr. Charles E. Stewart, director of the Battle Creek Sanitarium, Battle Creek, has announced that he will retire at the end of the year, newspapers reported. Until then Dr. Stewart will serve as adviser to Dr. John E. Gorrell, who was appointed administrator at the sanitarium in October 1939. Dr. Stewart joined the staff of the sanitarium in 1895; in 1917 he was made associate director and subsequently director.—Paul H. Jeserich, D.D.S., Ann Arbor, has been appointed a member of the state council of health for the term ending June 30, 1945, succeeding Dr. Carleton Dean, Charlevoix, who resigned recently to become deputy state health commissioner. Dr. Jeserich is president of the Michigan State Dental Society and director of postgraduate education at the University of Michigan School of Dentistry.

MINNESOTA

State Medical Election.—Dr. Berton J. Branton, Willmar, was chosen president-elect of the Minnesota State Medical Association at its annual meeting in Rochester in April and Dr. Bertram S. Adams, Hibbing, was installed as president. Drs. Albert Fritsche, New Ulm, and Frank J. Heck, Rochester, were elected vice presidents. The 1941 meeting will be in St. Paul. Dr. Carl W. Waldron, Minneapolis, was awarded the prize presented each year by the Southern Minnesota Medical Association for the best scientific exhibit at the state meeting. His theme was "Fractures of the Facial Bones."

MISSISSIPPI

Hospital News.—The Beacham Memorial Hospital was recently opened in Magnolia by Drs. Aubrey V. Beacham, Magnolia, Hugh T. and Woodard D. Beacham, New Orleans, all brothers, as a memorial to their father. Dr. George W. Robertson, Magnolia, made the principal address. Dr. Rudolph Matas, New Orleans, also spoke at the dedicatory ceremony.

MISSOURI

Personal.—Dr. Mary Jeanette Lower, Kansas City, was presented with the Award of Honor of the Soroptimist Club of Kansas City at a banquet in her honor, May 6. Dr. Lower is a charter member of the club, which is one of 175 similar organizations that make up the American Federation of Soroptimist Clubs of Professional and Executive Business Women. Membership is by invitation only and only one member of each classification is eligible.

Annual Clinic.—The St. Joseph Clinical Society held its ninth annual two day spring clinic at the Hotel Robidoux, St. Joseph, recently. The following participated:

Dr. Robert Elman, St. Louis, Intravenous Fluids in the Surgical Patient with Special Reference to Protein Replacement.
Dr. Emil D. W. Hauser, Chicago, Low Back Pain Due to Functional Decomensation.
Dr. Lee Forrest Hill, Des Moines, Iowa, Changes Produced by Severe Diarrhea and Their Reconstitution.
Dr. Virgil E. Simpson, Louisville, Ky., Criteria for Classification and Diagnosis of Heart Disease.
Dr. Leo G. Rigler, Minneapolis, Roentgen Diagnosis of Acute Abdominal Conditions and Bronchial Asthma.
Dr. William B. Kountz, St. Louis, The Heart and Vascular System in Middle Age and Its Importance in Clinical Medicine.
Dr. Paul A. O'Leary, Rochester, Minn., The Eczemas.
Dr. Joseph C. Birdsall, Philadelphia, Incidence of Urinary Tract Obstruction in Renal Disease.
Dr. Lester D. Powell, Des Moines, Consideration and Surgical Treatment of Uterine Prolapse.
Dr. Lathan A. Crandall Jr., Memphis, Tenn., Vitamin B and Functional Digestive Disturbances.

At a banquet the speakers were Dr. Simpson on "Chemotherapy of Pneumonia"; Dr. Charles W. Mayo, Rochester, "Malignancy of the Right Colon," and Dr. O'Leary, "The Treatment of Syphilis." Dr. Paul C. Barton, Director, Bureau of Investigation, American Medical Association, Chicago, addressed a pre-convention evening meeting on "Patent Medicines—Old and New."

NEW JERSEY

State Medical Meeting at Atlantic City.—The one hundred and seventy-fourth annual meeting of the Medical Society of New Jersey will be held at Haddon Hall, Atlantic City, June 3-6, under the presidency of Dr. Edward Zeh Hawkes, Newark. Among the speakers will be:

Dr. Hobart A. Reimann, Philadelphia, Functional Gastrointestinal Disorders.
Dr. Fritz H. Lewy, Philadelphia, Neurologic Manifestations of Nutritional Deficiencies.
Dr. Martin G. Vorhaus, New York, A Clinical Survey of the Vitamin B Complex and Its Components.
Dr. George P. Müller, Philadelphia, Complications of Peptic Ulcers: Diagnosis and Treatment.
Dr. Lewis C. Scheffey, Philadelphia, Problems Encountered in the Diagnosis and Treatment of Uterine Cancer.
Dr. Charles C. Higgins, Cleveland, Implantation of Ureters.
Dr. Thomas Fitz-Hugh Jr., Philadelphia, Gastrointestinal Disturbances in the Hemorrhagic Blood Dyscrasias.
Dr. William D. Stroud, Philadelphia, Gastrointestinal Disturbances in Cardiovascular Diseases.
Dr. Frank H. Lahey, Boston, Surgery of the Biliary Ducts and Their Complications.
Drs. Chevalier L. Jackson, William A. Swalm and Lester M. Morrison, Philadelphia, Gastritis, Diagnosis and Treatment.
Drs. Marion B. Sulzberger and Rudolf L. Baer, New York, Dermatologic Manifestations of Gastrointestinal Disease and Nutritional Deficiencies.
Dr. Samuel Bellet, Philadelphia, Effect of Tobacco Smoke and Nicotine on the Normal Heart and in the Presence of Myocardial Disease Produced by Coronary Artery Ligation: An Experimental Study in Dogs.
Dr. Sydney R. Miller, Baltimore, Chronic Nephritis and Its Treatment in the Light of Contemporary Renal Physiology.
Dr. Emil Novak, Baltimore, Endocrine Aspects of Primary Dysmenorrhea.
Dr. Leonard G. Rowntree, Philadelphia, Hyperinsulinism.
Dr. Edward L. Bauer, Philadelphia, Rheumatic Infections in Children.
Dr. Thomas A. Shallow, Philadelphia, Surgical Treatment of Gastric and Duodenal Ulcer.
Dr. Henry W. Cave, New York, Cancer of the Rectum.
Dr. Douglas P. Murphy, Philadelphia, Studies in Uterine Motility.
Arthur T. Vanderbilt, LL.D., Newark, professor of law, New York University Law School, will address a general session on "What Is Needed Now." The thirteenth annual meeting of the Woman's Auxiliary to the Medical Society of New Jersey will be at Haddon Hall, June 4-6.

NEW YORK

State Medical Election.—Dr. James M. Flynn, Rochester, was elected president of the Medical Society of the State of New York at the annual meeting in New York, May 7, and Dr. Samuel J. Kopetzky, New York, was chosen president-elect. It was necessary to elect a president because of the death of Dr. James H. Borrell, Buffalo, chosen president-elect at the 1939 meeting. Dr. Albert A. Gartner, Buffalo, was elected vice president and Dr. Peter Irving, New York, was reelected secretary. Next year's meeting will be in Buffalo.

Professor of Anatomy Appointed at Rochester.—Karl E. Mason, Ph.D., associate professor of anatomy at Vanderbilt University School of Medicine, Nashville, has been appointed professor and head of the department of anatomy at the University of Rochester School of Medicine and Dentistry, Rochester, N. Y., according to Science. He will succeed Dr. George W. Corner, who recently was appointed director of the department of embryology of the Carnegie Institution. Dr. Mason is a Canadian and took his doctor's degree at Yale University, New Haven, Conn., in 1925. He went to Vanderbilt in 1927 as instructor in anatomy; he became assistant professor in 1929 and associate professor in 1930.

New York City

Society News.—The program of the stated meeting of the New York Academy of Medicine, May 2, was devoted to "Problems of Aging." The speakers were Drs. George Morris Piersol, Philadelphia, on the general problem; Ernst P. Boas, Philadelphia, on the general problem; and Foster Kennedy, neuropsychiatric problems.—At a meeting of the New York Neurological Society with the section of neurology and psychiatry of the New York Academy of Medicine, May 7, the speakers were Drs. Hiram H. Merritt, Boston, and Tracy J. Putnam, or "Periodic Dulness as an Epileptic Equivalent"; Herbert Jasper, D.Sc., Montreal, Canada, "Electro-Encephalographic Localization of Focal Cerebral Lesions," and Dr. Lawrence S. Kubie, "The Repetitive Core of Neurosis."

Personal.—The staff of Morrisania Hospital gave a dinner, May 4, in honor of five members of its staff: Drs. Nathan B. Van Etten, President-Elect of the American Medical Association; Terry M. Townsend, immediate past president of the Medical Society of the State of New York; George E. Milani, president of the Bronx County Medical Society; Harry Aramow, member of the council of the state society, and William

siderations of the Use of Radiation Therapy with Reference to Some Specific Diseases."—Dr. Idys Mims Gage, New Orleans, addressed the Jefferson County Medical Society, Beaumont, in March, on "Abdominal Complications of Acute Appendicitis."—Speakers before the Dallas County Medical Society, April 25, included Drs. Arthur J. Schwenkenberg, Dallas, on "Metrazol and Insulin Treatment in Psychiatry" and Milford O. Rouse and Cecil O. Patterson, "Foreign Bodies of the Stomach Observed Through the Gastroscope."

WISCONSIN

Surgical Meeting.—The Milwaukee Society of Clinical Surgery held a joint meeting with the Wisconsin chapter of the International College of Surgeons, recently. Operative clinics were conducted at the Milwaukee County Hospital and in the afternoon and evening the following papers were presented:

GENERAL

Vitamin Research Prize Awarded.—A prize of \$1,000 offered by Mead Johnson and Company for advances in knowledge of the vitamin B complex was awarded at the annual meeting of the American Institute of Nutrition in New Orleans, March 13, for two achievements in investigation. The recipients were Dr. William H. Sebrell Jr., National Institute of Health, Washington, D. C., for the discovery of riboflavin and its use in keratitis; and a group from the research laboratories of Merck and Company, Rahway, N. J., for synthesis of vitamin B₆, now known as pyridoxine, John C. Keresztesy, Ph.D., Joseph R. Stevens, Ph.D., Stanton A. Harris, Ph.D., Eric T. Stiller, Ph.D., and Karl A. Folkers, Ph.D.

Parking Facilities for Physicians.—An "at the door" parking service will be available at the Grand Central Palace by the "20th Century Garage, Inc.," during the annual session of the American Medical Association in New York, June 10-14. This service has been created in order to relieve the parking problem of patrons and facilitates entrance to the Palace by car. Patrons drive to the main entrance where uniformed attendants deliver a claim check for cars and drive them to the garage. On departing the patron merely presents the claim check to the doorman, who telephones the garage and an attendant then delivers the car to the entrance of the Palace. The rates are as follows:

The rates are as follows:
Two hours 50 cents, 10 cents each hour thereafter; \$1 all day, \$1.50 for twenty-four hours. Special daily and weekly rates for exhibitors. Pick up and delivery charge included.

Association for Thoracic Surgery.—The annual meeting of the American Association for Thoracic Surgery will be held at the Hotel Statler, Cleveland, June 6-8. Included among the speakers will be: J. B. E. and Robert H. Wylie Jr.,

ne speakers will be:

Drs. Adrian V. S. Lambert, Edward P. Eglee and Robert H. Wylie Jr., New York, Empyema and Unexpanded Lung Problems in Pneumothorax.

Dr. David T. Smith, Durham, N. C., Treatment of Fungous Infections of the Lung.

Dr. Leo Eloesser, San Francisco, Further Experiences with Blocked Cavities in Pulmonary Tuberculosis.

Drs. Jacob J. Singer, John C. Jones, and Leon J. Tragerman, Los Angeles, Aseptic Pleural Adhesions Experimentally Produced.

Drs. Chevalier L. Jackson and Archibald R. Judd, Philadelphia, The Role of Bronchoscopy in the Treatment of Pulmonary Abscess.

Drs. Burr Noland Carter, Jean M. Stevenson and Osler A. Abbott, Cincinnati, Esophago-Gastrostomy—An Experimental Study.

Dr. J. H. Van Hook, New York, Fluoroscopic Radiography by

There will also be a symposium on bronchospirography by Drs. George C. Leiner and Max Pinner, New York, and William A. Zavod, Mount Vernon, N. Y.; David Salkin, Hopedale, W. Va., and Carl G. Merkel, Mount Morris, N. Y.

Academy of Tuberculosis Physicians.—The American Academy of Tuberculosis Physicians will hold its fifth annual meeting at the Commodore Hotel, New York, June 10-11, under the presidency of Dr. Benjamin P. Potter, Jersey City. The speakers will include:

The speakers will include:

Dr. Felix Baum, Newark, N. J., Rare Cases of Bilateral Idiopathic Spontaneous Pneumothorax in Nontuberculous Individuals.

Dr. Robert B. Mitchell Jr., Baltimore, Eversionation of the Diaphragm with Resembling Cardiac Disease.

Dr. H. Tubert, Paris, France, Sarcoids: Manifestations of Studies on the Possible Etiological Factors.

Dr. Jacob J. Schur, New York, The Scientific Determination of Erythrocyte Sedimentation Rate.

Dr. William F. Rienhoff Jr., Baltimore, Bronchiogenic Carcinoma.

Wilkes-Barre Postgraduate Conference.—Mercy Hospital, Wilkes-Barre, presented its seventh annual postgraduate conference, April 25, with the following speakers:

Dr. Belford C. Blaine, Pottsville, The Program of the Commission on Diabetes of the State Medical Society.
Dr. Joseph T. Beardwood Jr., Philadelphia, Diabetes as a Complication of Other Diseases.
Leon C. Chesley, Ph.D., Jersey City, N. J., Biochemistry of the Toxemias of Pregnancy.
Dr. M. Herbert Barker, Chicago, The Ionic Control of Edema.
Dr. John Scudder, New York, Shock: Blood Studies as a Guide to Therapy.

Philadelphia

Schmookler Lecture.—Dr. Marion B. Sulzberger, New York, delivered the Henry B. Schmookler Memorial Lecture at Mount Sinai Hospital, May 6, on "Some Present Concepts of Dermatologic Allergy, with Particular Reference to Their Application in Practice."

Society News.—The orthopedic section of the Philadelphia County Medical Society and the Baltimore Orthopedic Society held a joint meeting at Jefferson Medical College recently. The speakers were Drs. Charles C. Chapple, Philadelphia, on "Congenital Deformities in Children"; Morris Thomas Horwitz, Philadelphia, "Investigation of the Surgical Anatomy of the Knee Joint"; Benjamin Franklin Buzby, Camden, N. J., "End Results of Excision of the Elbow," and Edwin O. Geckeler, Philadelphia, "An Accurate Method of Subcutaneous Internal Fixation for Fracture of the Hip." The commentators, all of Baltimore, were Drs. I. William Nachlas, Allen F. Voshell, Harold R. Bohlman and George E. Bennett.—Dr. Howard B. Sprague, Boston, addressed the Philadelphia Heart Association at its annual meeting, April 10, on "Treatment of Congestive Failure During Active Rheumatic Infection" and Dr. Thomas M. McMillan reviewed the association's work during the past year.—Dr. Frank L. Apperly, Richmond, Va., delivered the annual conversational lecture of the Pathological Society of Philadelphia, April 11, on "The Chemical Function of the Stomach in Health and Disease."

TEXAS

Society News.—At a meeting of the Hunt-Rockwall-Rains Counties Medical Society in Greenville, April 9, the speakers were Drs. Lawrence W. Johnston, Terrell, on "Carbuncle of the Kidney"; Samuel D. Whitten, Greenville, "Superficial X-Ray"; and William M. Dickens, Greenville, "General Con-

VOLUME 114
NUMBER 21

Dr. George G. Finney, Baltimore, Lung Abscess.
Dr. James L. Dubrow, Des Moines, Iowa, Primary Bronchiogenic Carcinoma.
Dr. Ephraim T. Lisansky, Baltimore, A Method of Case-Finding for General Use.

Meeting of Ophthalmologists.—The American Ophthalmological Society will hold its seventy-sixth annual meeting at The Homestead, Hot Springs, Va., June 3-5. The speakers will include:

Dr. Martin Hayward Post, St. Louis, Sterilization of Sharp Instruments by Chemical Solutions.
Dr. Derrick T. Vail Jr., Cincinnati, Anterior Scleral Staphyloma and Retinal Detachment Cured by Excision.
Dr. Charles M. Swab, Omaha, Death Following Operation for Cataract Report of Three Cases.
Dr. Phillips Thygeson, New York, Sulfanilamide Therapy of Inclusion Conjunctivitis.
Dr. Trygve Gundersen, Boston, Convalescent Blood for Herpes Zoster.
Dr. Frederick H. Verhoeff, Boston, A Case of Leptotrichosis Conjunctivae (Parinaud's Conjunctivitis) Without Glandular Involvement.
Drs. Harold G. Scheie and Francis Heed Adler, Philadelphia, The Site of the Disturbance of Tonic Pupils (Adie's Syndrome).
Drs. Peter C. Kronfeld, Chicago, C. K. Lin, and T. H. Luo, Peiping, China, The Protein Content of the Re-Formed Aqueous Humor in Man.

Red Cross Appeals for Funds.—The American Red Cross has issued a nationwide appeal for funds for a minimum war relief fund of \$10,000,000 to continue and expand essential activities on behalf of civilian victims of the hostilities in Europe. According to an announcement, the Red Cross had, May 6, spent close to \$1,500,000, most of it from reserve funds. More than \$300,000 additional had been spent by chapters in purchasing materials for production of relief supplies. Up to May 6 the 250,000 volunteer Red Cross workers had given more than 3,000,000 hours of their time since last September in the production of 447,000 warm garments and 2,261,000 surgical dressings. These supplies, along with tons of drugs and medicines, surgical instruments, x-ray equipment, ambulances, hospital tents, soap and other material have been shipped periodically to the Red Cross societies of war-affected countries. Aid is now being provided to Belgium, Luxembourg, Germany, Netherlands, Finland, France, Norway, England, Hungary and occupied Poland, Latvia, Lithuania, Rumania, and Yugoslavia. The announcement stated that the Red Cross societies of all countries involved in armed conflict in Europe have requested aid except Germany.

Special Society Elections.—Thorne M. Carpenter, Ph.D., Nutrition Laboratory, Carnegie Institution, Boston, was elected president of the American Institute of Nutrition at the annual meeting in New Orleans, March 13; Albert G. Hogan, Ph.D., Columbia, Mo., vice president, and Leonard A. Maynard, Ph.D., Ithaca, N. Y., secretary.—Dr. Stanhope Bayne-Jones, New Haven, Conn., was elected president of the American Association of Pathologists and Bacteriologists at the annual meeting in Pittsburgh, March 20. Dr. Samuel R. Haythorn, Pittsburgh, was chosen vice president and Dr. Howard T. Karsner, Cleveland, was chosen president-elect of the American Association for the Study of Goiter at the annual meeting in Rochester, Minn., was chosen president-elect of the place of the Association, April 15. Dr. Frank E. Rogers, Denver, became president. Boston was tentatively named as the place of the 1941 meeting.—Dr. Louis Hamman, Baltimore, was elected president of the Association of American Physicians at its annual meeting in Atlantic City, May 8. Other officers include Drs. James H. Means, Boston, vice president; Hugh J. Morgan, Nashville, Tenn., secretary, and William S. McCann, Rochester, N. Y., treasurer.

Reunions in New York.—The committee on university dinners announces that the following organizations have made definite arrangements for reunions during the annual session of the American Medical Association in New York:

Johns Hopkins University Medical School and Hospital, luncheon, June 12.
New York Post-Graduate Medical School, dinner, June 12.
Harvard Medical School, Boston, dinner, June 12.
Columbia University College of Physicians and Surgeons, New York, dinner, June 12.
Columbia University Medical School, Chicago, dinner, June 12.
Northwestern University Medical School, joint luncheon, June 12.
Phi Beta Pi and Alpha Upsilon Omega, joint luncheon, June 12.
Phi Chi, luncheon, June 13.
Alpha Kappa Kappa, dinner, June 15.
Kings County Medical Society, dinner, June 15.

Nu Sigma Nu medical fraternity will hold a luncheon, June 12, at the Yale Club and not at the Waldorf-Astoria, as announced in THE JOURNAL May 11, page 1941, according to a notice from Dr. Arthur F. Warren, 667 Madison Avenue, New York, president of the New York Alumni Association. Dr. Francis Carter Wood, New York, will speak on "Changing Medicine" and Dr. Stuart Graves, Tuscaloosa, Ala., "The

Fraternity." The alumni of the University of Minnesota Medical School will hold a dinner at 6 o'clock Wednesday evening, June 12, at the Brauhaus Restaurant, New York. Dr. Louis A. Hauser, 140 East Fifty-Fourth Street, New York, is chairman.

Seminar on Physical Therapy.—The eighth annual seminar of the Western Section of the American Congress of Physical Therapy will be held, June 3-4, at the Fairmont Hotel, San Francisco. The speakers will include:

Dr. Harry Glenn Bell, San Francisco, Treatment of Erysipelas by Ultra-violet Light.
Gerhard K. Rollefson, Ph.D., Berkeley, Calif., Nature and Chemical Effects of Ultraviolet Light.
John B. de C. M. Saunders, San Francisco, The Postural Syndrome.
Dr. Arthur Merton Bassett, San Francisco, Diathermy in the Treatment of Bronchitis and Bronchiectasis.
Dr. John R. Upton, San Francisco, Local Heating in Pelvic Pathology.
Dr. Eric Liljencrantz, San Francisco, Freezing in Malignancy.
Dr. Eric C. Risser, Los Angeles, Differential Diagnosis and Treatment of the Lumbosacral and Sacro-Iliac Pathology.
Dr. Joseph C. Jones Jr., San Francisco, Types of Low Back Pain and Sciatica Found in Association with Dislocations of Intervertebral Disks.
Dr. Verne T. Inman, San Francisco, Anatomic Discussion of Subluxations of the Spine: Manipulative Correction.
Dr. Mayo H. Soley, San Francisco, Anxiety States and Their Physiological Manifestations.
Dr. Ernest G. Lion, San Francisco, Physical Therapy in Psychiatric Practice.
Dr. Samuel F. Boyle, San Francisco, Orthoptics.
Dr. Charles I. Singer, Long Beach, N. Y., Role of Spa Therapy in Chronic Degenerative Diseases.
Dr. Lucile M. Eising, San Francisco, Pool Therapy for Arthritis.
Dr. Benjamin Paul Davies, Stanford University, Calif., Treatment of Injuries to the Soft Tissues.

Committee on Revision of the Pharmacopeia.—At the thirteenth meeting of the United States Pharmacopoeial Convention in Washington, D. C., May 14-15, the following were elected as members of the Committee on Revision of the United States Pharmacopeia, 1940-1950:

Dr. Henry G. Barbour, New Haven, Conn.
Dr. Walter A. Bastedo, New York, N. Y.
Dr. George D. Beal, Ph.D., Pittsburgh, Pa.
Francis E. Bibbins, B.S., Indianapolis, Ind.
Dr. Charles L. Brown, Merion Station, Pa.
Joseph B. Burt, Ph.D., Lincoln, Neb.
Dr. William B. Castle, Boston, Mass.
Dr. William B. Castle, Baltimore, Md.
Clifford W. Christensen, Ph.D., Columbia, Ohio.
Bernard V. Christensen, Ph.D., Philadelphia, Pa.
E. Fullerton Cook, Pharm.M., New York, N. Y.
Dr. Arthur C. DeGraff, Syracuse, N. Y.
Dr. Marion S. Dooley, Chicago, Ill.
Dr. Carl A. Dragstedt, New York, N. Y.
Dr. Leon Lascoff, Pharm.D., Lafayette, Ind.
Charles O. Lee, Ph.D., Buffalo, N. Y.
Asa B. Lemon, Pharm.D., Baltimore, Md.
Dr. Perrin H. Long, Baltimore, Md.
Dr. Eli K. Marshall Jr., New Orleans, La.
Dr. George W. McCoy, New Orleans, Mass.
Dr. Walter L. Mendenhall, Boston, Mass.
Hugh C. Muldoon, Sc.D., Pittsburgh, Pa.
Dr. Erwin E. Nelson, New York, N. Y.
E. L. Newcomb, Pharm.M., New York, N. Y.
Charles Leonard O'Connell, Pharm.D., Pittsburgh, Pa.
Justin L. Powers, Ph.D., Washington, D. C.
Andrew G. DuMez, Pharm.D., Baltimore, Md.
Robert P. Fischel, Pharm.D., Trenton, N. J.
Perry A. Foote, Ph.D., Gainesville, Fla.
Dr. Harry Gold, New York, N. Y.
Forest J. Goodrich, Ph.D., Seattle, Wash.
Lloyd E. Harris, Ph.D., Norman, Okla.
Thomas J. Hill, D.D.S., Cleveland, Ohio.
M. L. Jacobs, Ph.D., Chapel Hill, N. C.
Glenn L. Jenkins, Ph.D., Minneapolis, Minn.
Charles B. Jordan, D.Sc., Lafayette, Ind.
John C. Krantz Jr., Ph.D., Baltimore, Md.
Henry A. Langenhan, Ph.D., Mercer Island, Wash.
J. Allen Reese, Ph.D., Richmond, Va.
Leon W. Richards, Ph.D., Missoula, Mont.
George C. Schicks, Ph.C., Upper Montclair, N. J.
Carl L. A. Schmidt, Ph.D., Berkeley, Calif.
A. John Schwarz, Ph.D., Memphis, Tenn.
Leonard A. Seltzer, Sc.D., Detroit, Mich.
Dr. Virgil E. Simpson, Louisville, Ky.
Dr. Isaac Starr, Philadelphia, Pa.
Frank O. Taylor, Ph.C., Detroit, Mich.
Dr. Soma Weiss, Boston, Mass.
Elmer H. Wirth, Ph.D., Chicago, Ill.
Heber W. Youngken, Sc.D., Boston, Mass.
Louis C. Zopf, Ph.G., Iowa City, Iowa.

CORRECTION

Shot in the Vermiform Appendix.—Dr. E. P. Hummel, Sterling, Colo., calls attention to a misnomer in the heading of the clinical note by Dr. John R. Earl, St. Paul, in THE JOURNAL, May 11, page 1864. Number 6 shot were found, not BB shot, as implied in the heading. BB shot are considerably larger than number 6.

LONDON

(From Our Regular Correspondent)

April 20, 1940.

Cranial Surgery at the Front

When the last war began we were quite unprepared for a military effort on such a gigantic scale. Now the danger has been foreseen and arrangements have been made in advance in the light of our experience of the last war. As previous letters have shown, this is true of the medical corps. The latest advance announced is a mobile unit for cranial surgery to operate as near the battle front as possible. Since the last war there have been many advances in technic, largely in the use of electrical apparatus, x-rays, diathermy and so on which will be made available. For cranial surgery the Royal Army Medical Corps has constructed a mobile neurosurgical unit which is self contained. The vehicle is a motor lorry which carries a separate engine and dynamo. The cable conveys the current to the operating room, where it is distributed to lighting, surgical diathermy, operation table heaters and suction pump. The current also charges a 12 volt accumulator for the electromagnet. The equipment includes two sets of instruments, two folding operating tables with special folding head rests, two folding instrument tables and modern anesthetic apparatus. Sterilization of water and instruments is done by oil stoves, and there is also a high pressure sterilizer for instruments and dressings.

The personnel traveling in the lorry includes a neurosurgeon, a neurologist, an anesthetist, two surgical assistants and two operating room nurses. The unit is designed to operate chiefly at casualty clearing stations but will be based on a parent base hospital for its reserve supplies. It carries sufficient material for several hundred neurosurgical operations and can thus remain in the forward area for weeks at a time.

The Greatest Evacuation in History

At the outbreak of the war the greatest evacuation in history—the removal from London and other centers to places of greater safety from air raids of 1,270,000 persons in four days—was briefly described. At the Royal Society of Medicine Dr. J. A. Glover, medical officer of the Ministry of Health, devoted his presidential address to the Section of Epidemiology and State Medicine to the epidemiologic aspects of this evacuation. Plans began to be formed at the time of the Munich crisis. The country was divided into eighty-one evacuation areas, 1,100 reception areas, chiefly small towns and rural districts, and neutral areas. The number of evacuable persons was estimated at 3,644,000, of whom half were school children. It was expected that 80 per cent would avail themselves of the official machinery (the evacuation was entirely voluntary). Offers to receive 2,000,000 school children in private houses were received. The Ministry of Health arranged with the local authorities for increased hospital provision for infectious diseases in the reception areas. For expectant mothers obstetric areas were defined according to accessibility to lying-in hospitals, and 137 maternity homes containing 3,700 additional beds were provided for normal cases. Consultant obstetric services and hospital accommodations were provided for abnormal cases. Arrangements were made for the prompt isolation of cases of puerperal pyrexia. An agreement was made with the British Medical Association for the domiciliary treatment of evacuated children. The Medical Research Council organized two central and twenty-three subsidiary laboratories to augment existing facilities. In many areas water supplies, sewerage and drainage were organized.

Of the evacuable population only one third was willing to go and on August 31 and the three following days 1,270,000 went to the reception areas. Of this number 166,200 were mothers

or other adults who accompanied 260,300 young children, 12,291 were expectant mothers and 734,883 were school children unaccompanied by their mothers. The remainder, apart from 5,000 blind and crippled persons, were teachers and other helpers. The school population of the reception areas was increased from 1,958,000 to 2,693,000.

The most imminent risk to those evacuated seemed to be the spread of poliomyelitis, diphtheria, scarlet and enteric fevers and dysentery. Diphtheria and scarlet fever had a high incidence in recent years and seemed likely to flare up when town carriers and country susceptibles mixed. But the incidence of infectious diseases in the first four months of the war was remarkably low. It was fortunate that evacuation took place at the beginning of September, one of the most healthful periods of the year as regards droplet infections, such as measles, whooping cough and influenza. The incidence of poliomyelitis was only a third and of diphtheria and scarlet fever only two thirds of that for 1938. The result bore out the soundness of the policy of dispersal in billets. All previous experience showed that concentration of children in camps would have given much less satisfactory results as regards infectious diseases.

Fatal Mercurial Poisoning After Cystoscopy

From the London Hospital Mr. B. H. Page and Mr. Clifford Wilson report in the *Lancet* three cases of fatal mercurial poisoning after cystoscopy, in which mercuric oxycyanide was used. Two of the cases occurred in 1938 and it was these which suggested the cause of death in the other, which occurred in 1935. The symptoms are illustrated by the following case: A man aged 58 complained of abdominal pain and difficulty in micturition. A vesical calculus had been removed five years before. Cystoscopy was performed under local anesthesia and the bladder was found normal except for fine trabeculation. From 8 to 10 ounces (about 250 cc.) of a 1:4,000 solution of mercuric oxycyanide was run into the bladder and left there. Twenty-four hours later the patient was admitted to the hospital with abdominal pain and inability to pass urine. He passed 4 ounces (120 cc.) of dark colored urine three hours after the cystoscopy, after which he was completely unable to micturate. He was in considerable distress with sunken cheeks and a dry furred tongue, but the temperature was normal. There were lower abdominal distention and some tenderness in the hypogastrium. Catheterization yielded 18 ounces (530 cc.) of blood stained urine. Vomiting, bloody diarrhea and suppression of urine followed. The blood urea rose to 600 mg. per hundred cubic centimeters of blood and he died on the thirteenth day. The necropsy showed ulcers in the bladder and colon and cloudy swelling of the kidneys. Mercurial solutions are widely used in cystoscopy and at the London Hospital extend back thirty years. Poisoning from their use appears to be extremely rare, but it is possible that instances have escaped recognition. Other patients were examined cystoscopically at the London Hospital on the same day and with the use of the same solution with no ill effects observed. Page and Wilson suggest that in their cases idiosyncrasy to the drug, possibly combined with abnormal retention and absorption, may have caused the fatalities. Whether this was so or not, there is no doubt that the use of mercuric oxycyanide solution in cystoscopy is dangerous.

The Effects on the Ears of Flying

Medical officers are studying the effects of war flying on the ears of pilots. Recent experiences show that modern high performance airplanes, with their capacity for fast climbing and fast diving, subject the ears of pilots to considerable strain. Those who are suffering from colds and make a high speed climb on interception duty may contract tympanic trouble, and methods for their protection are being considered. In the large bombing airplanes long periods of flying in intense cold have

been found to affect the ears of some of the crew. Also the noise of the engines may reduce their staying powers. Methods of silencing have been developed for civil as well as military machines.

PARIS

April 20, 1940.

International Medical Relations

The Association for the Development of Medical Relations recently held its annual meeting with Professor Tiffeneau, dean of the Faculty of Medicine of Paris, presiding. The chairman's address included the following statements: Persecutions, deportations, executions and brutal force cannot enslave thought. International cooperation in science as in all other activities implies confidence and good faith, qualities now undermined by unbridled propaganda, threats and treachery. The forces of destruction must be challenged by the forces of creative activity. French education needs ceaselessly to be improved and the doors of French hospitals and laboratories need to be widely opened. Paris has remained a center which attracts many. Not only exiled physicians and educators but many others desiring to work in an atmosphere of freedom have enrolled to continue their studies; also prominent foreigners have come to teach. On the other hand, France has sent its medical representatives into foreign countries, particularly into Latin America, with advantages to both sides. Professor Peck, the speaker said, visited Paris during the past year with the members of the International Postgraduate Assembly of North America, as well as another distinguished group of American physicians directed by Dr. Thomas D. Walker. The association had been founded in 1919 with the presence of many American physicians and counted many members in all countries. In 1926, when a French-Japanese center was founded in Tokyo, a representative of the medical profession was requested by the Japanese government. The relations thus established proved remarkably satisfactory. Since physicians in all countries have the same objective, namely to know truth in order to do good, and since medicine knows no political or ideologic frontiers, there is a pertinence in suggesting that medical attachés be added to the military and consular attachés representing the nation abroad. The speaker also called attention to the fact that Louis Dartigues, one of the founders of the Union médicale latine in 1912 and known and esteemed for his devotion to the idea of a worldwide medical cooperation, recently died.

Carotid Sinus Enervation

The region of the carotid sinus, according to a recent paper of Lucien Léger, is not a simple vascular bifurcation. It is, above all, the point of departure for a series of reflexes with neurovegetative repercussions. Tschermak's test disclosed some of them, especially those related to the system that regulates blood pressure. The ends of the sinus nerve within the carotid gland are endowed with a chemical sensitivity which Dautrebande succeeded in dissociating from sensitivity to mechanical stimuli. The carotid gland seems to possess an endocrine function not yet sufficiently defined. Lauwers had shown that the favorable results obtained in epilepsy by surgical intervention on the carotid sinus depended more on the site where intervention occurred than on its extent. His conclusions were that intervention should not be directed to the walls of the artery but should endeavor to suppress directly the nerve that connects the carotid sinus with the neural axis. From this idea had sprung several technics for the ablation of the carotid gland. The surgical problem consisted in avoiding injury to the arterial bifurcation and to the carotid gland or its vessels. Lauwers also combined sections of the sinus nerve and that of the external carotid with ablation of the carotid gland in order to facili-

tate access to the sinus and to increase simultaneously the output of the two internal carotid nerves.

Léger, however, rejects the section of the carotid nerve, recently proposed by Cordier and Coulouma, as complex and perhaps illusory. He performs the enervation of the sinus nerve at the point where the nerve joins the bifurcation and not at some distance. He rejects chloroform and accepts ether but prefers local anesthesia. It is mandatory to infiltrate the outer carotid coat and the tissue comprised within the vascular carotid bifurcation with a procaine hydrochloride solution free from epinephrine. It is better to operate twice if a bilateral operation is involved. A good test of the success of the enervation is the hemorrhage induced by the section of the artery of the carotid gland. Additional tests consist in histologic controls and in examining digitally the sensitivity of the tissues to mechanical stimuli. Ablation of the carotid gland carries with it only insignificant and temporary modifications of arterial tension, but the danger of syncope is present. This can be prevented only by extreme operative care and ample infiltrations of anesthesia. This operation is indicated especially in epilepsy, also in transitory cerebral anemia attended by convulsive crises. Léger's statistics include eighty-two cases with fifteen cures (18.7 per cent) observed for at least ten years, twenty-three improvements (26.2 per cent), forty-three failures (53.9 per cent) and one death (1.2 per cent).

Death of Eugène Apert

Dr. Eugène Apert, a physician known for his contributions to children's and hereditary diseases, died at an advanced age.

BERLIN

(From Our Regular Correspondent)

April 12, 1940.

Medicine on Wheels for Rural Communities

In the Danube region formerly belonging to Austria, a so-called health wagon has been put into use among the farming communities. It consists of an automobile in which the rear seats have been removed and a medicine chest built in containing medical instruments, a scale for weighing children and a card index of the mothers and children in the various villages. The physician is his own chauffeur. He is accompanied by a social welfare nurse. The service cares for infants and preschool children and offers advice to mothers similar to that given in maternity and children's welfare stations in cities. Children receive medical care from the time they are born to the fourteenth year. Particular attention is paid to rickets and digestive disturbances. The work is done in close cooperation with the physicians and hospitals of the district. Similar health vehicles are planned for other Austrian districts. The villages and settlements are visited in regular rotation, about every two weeks on the same day. The medical service is free.

Psychopathologic War Reactions

Recently Dr. F. G. von Stockert reported to the medical society of Frankfurt on the Main observations made in the psychiatric ward of the military garrison of Frankfurt of the first 100 patients received in the first two months of the war. He compared these observations with those made in peace times and in 1914. Fewer alcoholic cases were found than in 1914. In the first week of the war two suicides and three deaths from emotional instability, due to anxiety, occurred. Similar psychopathic reactions have frequently been observed during the first few months when recruits were drafted for military training in peace times. Experiences shows that hysterical reactions do not begin to accumulate until after a war has been in progress for some weeks. These hysterias are largely monosymptomatic. In the treatment of these cases it is important to check its evolution; for example, not to allow mutism to become aphonia.

Student Regimentation

Labor conscription has been imposed on all students, effective in 1940, according to Dr. Scheel, national student leader. Until they have completed their education and can be mobilized for active soldiering, students must do duty during the first three semesters in unloading freight trains carrying coal or foodstuffs, in agriculture and forestry, in aviation, in technical emergency aid and so on. Students are formed into groups of from thirty to forty men according to their curriculums and then assigned. These activities obviously have no relation to their studies. It is also emphasized that students will be rated according to their efficiency. "Useless parasites" will be severely dealt with.

Students will also be conscripted for propaganda purposes. Participation in present day political problems is made a student obligation. For that reason students must stress, for the duration of the war, the study of the history and culture of other nations, including England, in order to track down arguments that may be used against England.

Race and Diabetes

H. Lemser recently compiled comparative data of various countries to determine what part the environment and what part race played in the diabetic picture. Diabetes is found in all races that have been sufficiently studied. Racial differences, no doubt, are determining factors in the incidence of diabetes; for example, in the case of the Jews. But this incidence is not easy of demonstration because of the lack of adequate information regarding environmental and hereditary factors and of non-European races. Of greater significance are the degree of gravity of the disease and its evolution. The former is essentially hereditary and scarcely modifiable by the environment. No definite theories can yet be formulated regarding the effect of race mixture on diabetes.

Additional Regulations on Medicines

According to a new ministerial decree, liver preparations intended to combat pernicious anemia and other diseases may now be dispensed only on prescription. The same regulations apply to benzedrine and its salts and to medicines containing these drugs and to iodine compounds and their preparations, except that a new prescription is required each time. For reasons of economy during the war, tincture of iodine must be doubly diluted with alcohol unless the undiluted form is expressly called for by the physician. The content of boric acid in boric acid ointment has been reduced from 10 per cent to 3 per cent (THE JOURNAL, Dec. 30, 1939, p. 2436).

AUSTRALIA

(From Our Regular Correspondent)

April 9, 1940.

Blood Bank for Overseas Army

The Australian Red Cross Society's gift of a mobile blood bank to the second Australian Imperial Force will enable transfusion to be brought into use nearer the front line and much earlier than ever before. The unit has now been officially handed over to the army. The blood bank, for which £1,550 was collected throughout Australia, comprises a blood transport and refrigerating van which carries eighty bottles of stored blood, and a service vehicle providing facilities for sterilization, distillation of water, repair of transfusion apparatus and the collection of blood from donors.

Early Tuberculosis in Army Recruits

In accordance with the decision of military medical authorities to carry out x-ray examinations of the chests of army recruits who will subsequently proceed overseas, the first batch were examined early this year. The technic employed was to photograph on 35 mm. film the shadow thrown on a fluorescent

screen. Expedition was imperative, and 2,220 were examined in one day with the assistance of fifteen technicians and three record clerks. Examining teams consisting of a physician and a radiologist sat almost continuously for five days. Of a total of 6,775 recruits examined, 0.49 per cent were rejected on evidence obtained by this method. Some doubt was expressed by the radiologists as to whether the 35 mm. film was satisfactory in its present stage of development. Of 6,622 men examined on the miniature film, 365 were classified as doubtful, and when subsequently retaken on 17 by 14 inch film 342 were accepted and twenty-three rejected. Only ten were rejected on the miniature film alone. It was felt that a 4 by 5 inch photograph of the fluoroscopic shadow would be easier to examine, and the large number of retakes on 17 by 14 film would in this way be avoided.

National Health Drive

A health education campaign through press, radio and cinema is part of the plan for a nationwide health drive conceived by the commonwealth and state health authorities in Australia. It has the support of local branches of the British Medical Association. The object of this educative campaign is to inform the public of the preventive and curative medical and health services available. It will also stress the importance to the nation of preserving a high individual health standard. The eradication of tuberculosis by uniform preventive and remedial measures in all states is another aim. Results of the x-ray examination of army recruits had shown that incipient tuberculosis was prevalent among apparently robust men to the alarming extent of one in every 200. This might justify the extension of x-ray examination to make it available also for civilians. Tuberculosis should not be a major health problem in Australia. Australia's sunshine and pleasant weather assist in curing lung disorders. We have adequate supplies of fresh foods, and living conditions are good. With the medical skill and technical equipment now available, there is no reason why an adequate coordinated effort should not stamp out tuberculosis within fifteen years. The problem of venereal disease, the relation of animal diseases to domestic health and the control of various epidemic diseases are included in the plan for coordinated action.

UNIFORM REGISTRATION OF DOCTORS

Complete uniformity in the registration of medical practitioners, nurses, dentists, chemists, optometrists and veterinary surgeons throughout the commonwealth is also proposed. This, however, does not involve any radical alteration in existing conditions. At present conditions of practice in all these professions are similar in all states but uniform regulations would be advantageous.

Marriages

BENJAMIN BRUCE LANGDON, Fayetteville, N. C., to Miss Helen Browne Bennett of Chevy Chase, Md., March 23.

ALBERT V. STOESEER, Minneapolis, to Miss Marie Druckrey of Green Bay, Wis., in Shawano, Wis., April 27.

EDWIN W. ROBERTS, Watertown, N. Y., to Miss Mildred Marie Miller in Philadelphia recently.

JOHN R. TALBOT, Richmond, Va., to Miss Anne Virginia Bellows of White Stone, March 10.

EDWARD STEPHEN STANLEY to Miss Elizabeth Holman, both of San Angelo, Texas, January 18.

BERNARD E. BOLOTOFF, Rockford, Ill., to Miss Mary Younkus in East Chicago, Ind., in March.

WAYNE REESER, Lubbock, Texas, to Miss Evelyn Clayton Craft of Dallas recently.

HUGH H. TROUT JR. to Miss Elizabeth Page Browne, both of Roanoke, Va., April 6.

JOHN B. BOURLAND to Miss Mabel Sanders, both of Dallas, Texas, January 17.

DEATHS

Deaths

George Alder Blumer • Providence, R. I.; University of Pennsylvania Department of Medicine, Philadelphia, 1879; L.R.C.P. and L.R.C.S., Edinburgh, Scotland, 1884; past president of the American Medico-Psychological Association, Boston Society of Psychiatry; member of the American Psychiatric Association; honorary member of the Royal Medico-Psychological Association of England, the Society of Mental Medicine of Belgium and the Medico-Psychological Society of Paris; corresponding member of the Society of Psychiatry at the Albany (N. Y.) Medical College; superintendent and formerly lecturer and adjunct professor of insanity at the (N. Y.) State Hospital from 1886 to 1899; superintendent and physician in chief to the Butler Hospital from 1899 to 1922 and since 1922 emeritus superintendent; editor emeritus of the *American Journal of Psychiatry*; aged 82; died, April 25, in the Jane Brown Hospital of arteriosclerosis.

Henry Clarke Coe, Washington, D. C.; Harvard Medical School, Boston, 1881; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1882; M.R.C.S., England, 1884; professor emeritus of gynecology at the New York University College of Medicine, formerly known as the University and Bellevue Hospital Medical College, New York, where he was professor of gynecology from 1896 to 1915; past president of the American Gynecological Society; member of the founders and governor from 1927 to 1930 of the American College of Surgeons; served during the World War; consulting gynecologist to the Bellevue, Woman's, Polyclinic, Beth Israel and Memorial hospitals, New York; co-author with Dr. Keating of "Clinical Gynecology," published in 1894; aged 84; died, April 20, of heart disease and arteriosclerosis.

Thomas P. Farmer • Syracuse, N. Y.; Syracuse University College of Medicine, 1906; member of the House of Delegates of the American Medical Association from 1933 to 1935 and from 1937 to 1939; professor of clinical gynecology; on alma mater; fellow of the American College of Surgeons; on the staffs of the Syracuse Memorial Hospital, St. Joseph's Hospital, Syracuse Free Dispensary and the Syracuse Psychopathic Hospital; at one time health officer; aged 56; died, April 12, of carcinoma of the axilla.

Henrietta Tucker Tanner, Philadelphia; Bennett College of Eclectic Medicine and Surgery, Chicago, 1898; Woman's Medical College of Pennsylvania, Philadelphia, 1922; member of the Medical Society of the State of Pennsylvania; at various times on the staffs of the Northwestern General Hospital, Woman's Hospital and the Germantown Hospital; aged 63; died, March 9, of coronary occlusion.

Laurence James Dervin, Somerville, Mass.; Ludwig-Maximilians-Universität Medizinische Fakultät, München, Bavaria, Germany, 1903; member of the Massachusetts Medical Society and the New England Pediatric Society; formerly teaching assistant in pediatrics at the Tufts College Medical School, Boston; aged 63; died, March 30, in the Somerville (Mass.) Hospital of heart disease.

John M. Quigley, Clearfield, Pa.; Baltimore Medical College, 1898; member of the Medical Society of the State of Pennsylvania; past president and secretary of the Clearfield County Medical Society; for many years medical examiner of the public schools; formerly president of the board of health of Clearfield; on the courtesy staff of the Clearfield Hospital; aged 65; died, March 17.

Nelson Borst, Poughkeepsie, N. Y.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1890; member of the board of health and school board; formerly member of the Vassar Brothers Hospital and St. Francis Hospital; aged 83; died, March 28, in Miami, Fla., of myocarditis.

Charles Edgar Chandler, Hamilton, Texas; Memphis (Tenn.) Hospital Medical College, 1908; member of the State Medical Association of Texas; served during the World War; city health officer; formerly county health officer; for many years member of the school board; medical superintendent of the Hamilton Sanitarium; aged 54; died, March 26, of coronary occlusion.

Carl Kurtz, Los Angeles; Bellevue Hospital Medical College, New York, 1889; fellow of the American College of Surgeons; at one time professor of gynecology at the University

of Southern California School of Medicine; formerly member of the board of education and board of health; aged 71; died, March 2, in the California Hospital of chronic myocarditis.

John Newton Boyce, Poughkeepsie, N. Y.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1895; member of the Spanish-American and World wars; on the staff of the Vassar Brothers Hospital; aged 66; died, March 29, of coronary thrombosis.

Thomas Tweed Warham • Minneapolis; Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1897; an Affiliate Fellow of the American Medical Association; formerly county physician; aged 73; died, March 27, of coronary sclerosis, diabetes mellitus and chronic pulmonary tuberculosis.

Frederic Purdy Hollister, Scranton, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1899; member of the Medical Society of the State of Pennsylvania; past president of the Lackawanna County Medical Society; on the staff of the Scranton State Hospital; aged 67; died, March 26, of angina pectoris.

Clifford James Ulshafer • Shenandoah, Pa.; Temple University School of Medicine, Philadelphia, 1930; fellow of the American College of Surgeons; surgeon in chief and chief of the staff of the Locust Mountain State Hospital; aged 38; died, March 1, in the Temple University Hospital, Philadelphia, of pneumonia.

Raphael Frederick Medrick, Port Jervis, N. Y.; University of Pennsylvania Department of Medicine, Philadelphia, 1895; member of the Medical Society of the State of New York; on the staff of the Deerpark Hospital, where he died, March 21, of chronic nephritis and hypertrophy of the prostate.

Leonard Ezra Curtice, Buffalo, 1897; member of the Medical Department, Buffalo, 1897; on the staff of the Millard Fillmore Hospital; aged 71; died, March 30, in the Buffalo General Hospital of coronary occlusion.

William Angelo Sparks, Birmingham, Ala.; Medical College of Alabama, Mobile, 1905; member of the Medical Association of the State of Alabama; veteran of the Spanish-American War; aged 64; died, March 29, in the Veterans Administration Facility, Tuscaloosa.

Horace Edmund Schlemm, Long Beach, Calif.; Jefferson Medical College of Philadelphia, 1886; at one time a member of the school board of Reading, Pa.; formerly on the staff of the Reading (Pa.) Hospital; aged 80; died, March 12, of cerebral hemorrhage.

Olive Whitney Wheaton, Huntington, N. Y.; Cornell University Medical College, New York, 1928; member of the Medical Society of the State of New York; on the staff of the Huntington Hospital; aged 43; died, March 2, of a streptococcal infection.

Joseph Arthur Collie, Pasadena, Calif.; Northwestern University Medical School, Chicago, 1898; for many years resident physician at the Las Encinas Sanitarium; veteran of the Spanish-American and World wars; aged 74; died, March 5, of military tuberculosis.

Willis Johnson Middleton, Acton, Mass.; Tufts College Medical School, Boston, 1901; assistant in anatomy at his alma mater from 1902 to 1905; for many years on the staff of the Quincy (Mass.) Hospital; aged 71; died, March 14, of heart disease.

Wallace Harden Smith, Natchez, Miss.; University of Tennessee College of Medicine, Memphis, 1929; member of the Mississippi State Medical Association; on the staff of the Natchez Sanitarium; aged 34; died, March 24, of anaphylactic shock.

Byron O. Nobles, Milwaukee; Northwestern University Medical School, Chicago, 1893; at one time professor of obstetrics at the Milwaukee Medical College; aged 76; died, March 23, of chronic myocarditis, arteriosclerosis and broncho-asthma.

Charles Augustus Orr, Excelsior Springs, Mo.; National University of Arts and Sciences Medical Department, St. Louis, 1913; member of the Missouri State Medical Association; aged 67; died, March 11, in Knoxville, Iowa, of duodenal ulcer.

George Waldo Burgess, Guerneville, Calif.; Cooper Medical College, San Francisco, 1895; veteran of the Spanish-American War; aged 70; died, March 7, in the Southern Pacific General Hospital, San Francisco, of carcinomatosis.

John Anderson Bowles, Tacoma, Wash.; Washington University School of Medicine, St. Louis, 1907; member of the Washington State Medical Association; served during the World War; aged 58; died, February 2, of a broken back.

Richard Coleman Ditto, Oakville, Iowa; Keokuk Medical College, College of Physicians and Surgeons, 1901; member of the Iowa State Medical Society; aged 66; died, March 28, in the Burlington (Iowa) Hospital of myocarditis.

Forster Hanson Smith, Lowell, Mass.; Harvard Medical School, Boston, 1902; formerly superintendent of the Lowell Tuberculosis Hospital; aged 62; died, March 17, of wounds of the throat and wrist self inflicted with a razor.

Foster Harris Kennedy, Wellsboro, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1911; member of the Medical Society of the State of Pennsylvania; aged 54; died, March 9, of pulmonary embolism.

Samuel R. Phillips, Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1905; member of the Medical Society of the State of Pennsylvania; aged 57; died, March 22, of coronary thrombosis and diabetes mellitus.

Sidney Archer Lord, Boston; Harvard Medical School, Boston, 1894; member of the Massachusetts Medical Society; formerly on the staff of the Massachusetts General Hospital; aged 70; died, March 30, of pneumonia.

Solomon P. Hakes Ⓢ Tioga, Pa.; University of the City of New York Medical Department, 1888; formerly secretary of the Tioga County Medical Society; bank president; aged 78; died, March 14, of arteriosclerosis.

James Wooten Smith, Poth, Texas; Medical College of Virginia, Richmond, 1901; member of the State Medical Association of Texas; aged 60; died, February 25, of injuries received in an automobile accident.

Alvin Joseph Brah Ⓢ Milwaukee; Wisconsin College of Physicians and Surgeons, Milwaukee, 1908; on the staff of St. Joseph's Hospital; aged 53; died, March 26, of chronic valvular heart disease and myocarditis.

Mary Forrester Hobart, Needham, Mass.; Woman's Medical College of the New York Infirmary for Women and Children, New York, 1884; aged 88; died, March 21, of uremia due to cardiorenal degeneration.

Archibald Carter Long, Sheridan, Mo.; Ensworth Medical College, St. Joseph, 1900; aged 70; died, March 28, in the Missouri Methodist Hospital, St. Joseph, of pulmonary edema and arteriosclerotic heart disease.

Henry David Hulley, Griswold, Iowa; University of Nebraska College of Medicine, Omaha, 1902; member of the Iowa State Medical Society; aged 68; died, March 23, of organic heart disease.

John Daniel Hare, Reedley, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1890; aged 82; died, February 3, of chronic cystitis, retention of urine and heart disease.

Jean Harris Whitney Morse, Redwood Falls, Minn.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1897; aged 67; died, March 27, of cerebral hemorrhage.

Anna Samnilovna Wilner, Rockaway Beach, N. Y.; Woman's Medical College of the New York Infirmary for Women and Children, New York, 1895; aged 66; died, February 9.

Elmer Howard Hankey, Pittsburgh; College of Physicians and Surgeons, Baltimore, 1914; aged 51; died in March in the Western Pennsylvania Hospital of cirrhosis of the liver.

James M. Gober, Beaumont, Texas; Kentucky School of Medicine, Louisville, 1894; aged 74; died, March 21, in St. Therese Hospital of injuries received in an automobile accident.

John George McFadden, Loveland, Colo.; Western Reserve University Medical Department, Cleveland, 1894; aged 70; died, March 4, of carcinoma of the prostate and uremia.

Edith Sturges Heller, West Hartford, Conn.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1894; aged 73; died, February 29, of cerebral hemorrhage.

Thomas Jefferson Turpin, Chihuahua, Mexico; Kentucky School of Medicine, Louisville, 1869; Jefferson Medical College of Philadelphia, 1870; aged 92; died, March 5, of senility.

Clarence Eugene Hight, Pasadena, Calif.; Medical School of Maine, Portland, 1900; served during the World War; aged 65; died, March 15, of rheumatic heart disease.

Monroe J. Polk, New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1895; died, March 4, of coronary thrombosis.

William Lewis Stephens, Meridian, Calif.; Eclectic Medical Institute, Cincinnati, 1901; formerly county health officer; aged 67; died, March 18, of cerebral hemorrhage.

Houston E. Snyder, Glens Ferry, Idaho; Western Eclectic College of Medicine and Surgery, Kansas City, Kan., 1909; aged 56; died, March 26, of heart disease.

Denis Joseph McMahon, Breckenridge, Minn.; College of Physicians and Surgeons, Keokuk, Iowa, 1894; aged 70; died, March 12, of carcinoma of the throat.

Herbert R. Flint, Hornell, N. Y.; University of Buffalo School of Medicine, 1882; for many years health officer; aged 86; died, March 28, of heart disease.

Herbert Chester Thomas, Altoona, Pa.; Jefferson Medical College of Philadelphia, 1915; aged 48; died, March 15, in the Mercy Hospital of osteomyelitis.

John Kercher, Chicago; Chicago Medical College, 1890; member of the Illinois State Medical Society; aged 77; died, March 20, of arteriosclerosis.

Stephen Edwin Peters Ⓢ Masontown, Pa.; Chicago College of Medicine and Surgery, 1909; aged 56; died, March 13, of coronary artery occlusion.

Charles Abram Bozarth, Mason City, Iowa; Hahnemann Medical College and Hospital, Chicago, 1886; aged 86; died, March 28, of myocarditis.

Henry Beier, Huntington Park, Calif.; St. Louis University School of Medicine, 1918; aged 46; died, February 23, of coronary thrombosis.

James Henry Kelley, Flemingsburg, Ky.; Hospital College of Medicine, Louisville, 1892; aged 69; died, March 22, of pernicious anemia.

James A. Printy, Flushing, N. Y.; State University of Iowa College of Homeopathic Medicine, Iowa City, 1882; aged 85; died, February 12.

Edward Lorne McIntyre, High Prairie, Alta., Canada; University of Toronto Faculty of Medicine, 1911; aged 53; died, February 1.

Thomas Erlin Kaiser, Oshawa, Ont., Canada; Victoria University Medical Department, Coburg, 1890; aged 76; died, February 29.

Henry W. Coffin, Glens Falls, N. Y.; New York Homeopathic Medical College, New York, 1881; aged 80; died, February 17.

James Mitchell Nairn, Toronto, Ont., Canada; Victoria University Medical Department, Coburg, 1886; aged 81; died, February 12.

Ernest Wilson McNiece, Aylmer (West) Ont.; Western University Faculty of Medicine, London, 1918; aged 49; died, January 20.

Paul Ewert, Golden, B. C., Canada; McGill University Faculty of Medicine, Montreal, Que., 1912; aged 56; died, February 4.

James Robertson, Montreal, Que., Canada; Hahnemann Medical College and Hospital, Chicago, 1910; aged 62; died, February 5.

Moses Sylvester Howell, Greenville, Texas; University of Georgia Medical Department, Augusta, 1885; aged 77; died, March 8.

Jacob Louis Rubinstein Ⓢ New York; University of Maryland School of Medicine, Baltimore, 1904; aged 56; died, February 27.

Jesse Sturgeon, Salem, Ohio; Bellevue Hospital Medical College, New York, 1878; aged 86; died, March 13, of pneumonia.

Clyde Leverne Gillam, Rawlins, Wyo.; Marion-Sims College of Medicine, St. Louis, 1893; aged 67; died, February 28.

PULMONARY EMBOLISM FOLLOWING THE INJECTION TREATMENT OF VARICOSE VEINS

To the Editor:—The unprejudiced reader of Dean and Dulin's paper "Pulmonary Embolism Following the Injection Treatment of Varicose Veins" (*THE JOURNAL*, April 6, p. 1344) can easily get the impression that the treatment of varicose veins by injections is not as safe as pictured by "numerous authors" who "report a low incidence of complications following the injection therapy of varicose veins," that "the dangers of this procedure are greater than is usually reported" and that high ligation or other surgical procedure reduces fatal embolism. Drs. Dean and Dulin base their conclusions on their experience with two fatal cases among 600 cases treated by injection; they imply that deadly embolism might have been avoided by a proper treatment explained in their conclusions 2, 3, 4, 5 and 6. The physician who wants to treat varicose veins or has to recommend a certain procedure should get an impartial picture of the value or disadvantage of the different methods. This picture could have been obtained here if, besides the fact of "low incidence of serious complications following the injection therapy of varicose veins," the observations and conclusions of the authors and papers cited would have been reported. Let me examine what they say:

According to Westerborn's Swedish statistics, the only ones available which differentiate between treatment of varicose veins by (a) different operations, (b) high ligation and consecutive injection and (c) injection alone, the following percentages resulted in deadly embolism: Of 6,994 cases in which operation was done eighteen, or 0.26 per cent, were fatal; of 1,200 cases in which high ligation of the saphenous vein and retrograde injection were done four, or 0.33 per cent, were fatal, and of 30,000 cases in which injection alone was done eleven, or 0.036 per cent, were fatal. These statistics show a ten times higher mortality rate in cases of ligation than in cases of injection.

Kettel says in his cited paper that the extremely low mortality rate in cases treated by injection can be further reduced by proper precautions. With regard to the high ligation and retrograde injection treatment of varicose veins, he states that the mortality rises up to from 0.5 to 1 per cent, citing Berntsen, Kilbourne, Laqua, Reichel and others. He wrote "The majority of the authors [Meissen, Kilbourne, Fraenkel, Gruca, Baur, Vigyázó] reject the combined treatment by high ligation and injection."

Probststein, reporting three nonfatal cases of embolism of his own observation, quotes in the cited paper 120,000 injections of varicose veins in 15,000 consecutive cases observed by Sicard and Gaugier without a single mortality.

Silverman wrote "A search of the literature has revealed a total of only nineteen cases of embolism following in hundreds of thousands of cases."

Kilbourne reports that he did not have a single death in his clinic among 20,000 injections of varicose veins. He wrote about the high ligation "This simple ligation has its disadvantages. Ligation may cause a funnel-shaped blind pocket in the vein proximal to the ligature in which the blood stagnates, allowing a thrombus to form, and this thrombus is not well attached to the vein wall as is the firmly inrooted thrombus formed by injection of highly irritating solutions. A mortality rate results which I have shown is 0.5 per cent in larger series. This is not inconsiderable in such a small operation." He further states that he ligates "only occasionally giant veins which resist the sclerosing effect of injection." In the majority of cases of giant veins he prefers not to ligate.

In consideration of world literature, which to a large extent rejects the surgical treatment of varicose veins, and in view of the impressive statistics, one should be careful in recommending a risky method, especially as routine procedure. Reports from other authors are on hand regarding successful treatment of varicose veins by high ligation and retrograde injection. The number of such cases is still small. Surgeons convinced of the superiority of the surgical treatment over the injection treatment may continue to treat their patients with surgical methods. They should publish both their good results and their failures. In my opinion (*M. Rec.* 149:169 [March 1] 1939) embolism in the injection treatment of varicose veins can be reduced to an insignificant minimum. Effective and safe treatment of varicose veins and their sequelae requires experience, a proper technic and a suitable solution (*M. Rec.* 147:307 [April 6] 1938; *Arch. Dermat. & Syph.* 41:530 [March] 1940).

LUDWIG ISAAK, M.D., New York.

STOMACH LAVAGE IN TUBERCULOSIS

To the Editor:—In *THE JOURNAL*, April 13, page 1478, Dr. Kantor registered a complaint that workers in general, and we in particular (Stadnichenko, Cohen and Sweany: Stomach Lavage in the Diagnosis and Control of Treatment of Tuberculosis, *ibid.*, February 24, p. 634), did not give credit to Dr. Levy and himself for their work on tubercle bacilli in stomach contents. In 1915 Levy and Kantor (Tubercle Bacilli in Stomach Contents, *Arch. Diagnosis* 8:154 [April] 1915), seventeen years after the original work of Meunier was published (*Bacilloscopie des crachats extraits de l'estomac pour le diagnostic de la tuberculose pulmonaire de l'enfant, Presse méd.* 2:81, 1898), observed tubercle bacilli in the gastric contents of a tuberculous patient and "succeeded in demonstrating the organisms in this fashion in two other cases." No history or x-ray, clinical and laboratory examinations were mentioned in the three cases other than a mere mention of the tubercle bacilli. Even the ages of these patients are not given. For the latter reason alone, if for no other, we cannot agree with Kantor that "Prof. I. H. Levy is entitled to full credit for the idea" of reporting results on adults. Their observation might have been of interest to them, but their report did not contribute to the scientific knowledge of tuberculosis.

HENRY C. SWEANY, M.D., Chicago.

PEDIATRIC EMERGENCIES

To the Editor:—I have always had a great deal of regard for the writings of Dr. Joseph Brennemann. However, I am constrained to take exception to an opinion expressed in a recent special article, "Pediatric Emergencies" (*THE JOURNAL*, March 16, p. 956). In discussing the treatment of congenital atresia of the esophagus, Dr. Brennemann states "No child has ever lived, and with the consent of the parents one is justified in letting the child die without treatment." Granted that the prognosis is nil in these cases, that the posterior mediastinum is *terra incognita* as far as the surgeon is concerned and that any procedure in the posterior mediastinum is attended with formidable obstacles, nevertheless an attitude such as "letting the child die" has a defeatist and nonprogressive ring.

There are many procedures carried out at present which only fifty years ago would have appeared to be impossible. Practically every part of the human body has become by degrees and improvements in technic amenable to surgery—the abdomen, the brain, the vascular system, the nervous system, the lungs, the heart and why not finally that hidden area the posterior mediastinum?

Our task as physicians is to strive to maintain life against all odds and to aim at perfection in our work and nothing

short of perfection. If something appears hopeless and devoid of solution now, it may not be so in the future. There are too many such examples in the history of all sciences to enumerate.

MICHAEL A. BRESCIA, M.D., Queens, N. Y.

[Dr. Brennemann replies:]

To the Editor:—At the time my paper on pediatric emergencies was written, to my knowledge no child with congenital atresia had ever lived, and the duration of life was usually shortened by operation. On a recent trip to Minneapolis I saw, however, a baby that had been operated on three months before and was still living. In that case a gastrostomy had been done and a catheter had been passed some little distance beyond the pylorus, followed by a tying off of the lower end of the esophagus near the bifurcation of the trachea. I quite agree with Dr. Brescia that "our task as physicians is to strive to maintain life against all odds and to aim at perfection in our work and nothing short of perfection." Since the child on whom the operation I have just spoken of was performed may live for years and since an artificial esophagus can then be built, there is at least a hope that the child may live for a long time. There is probably no hope of ever connecting the upper and lower ends of the esophagus, as the lower end is usually very thin and atrophic. However, I quite agree, after seeing this child, that one should operate with the technic employed in this case or with some other procedure.

JOSEPH BRENNEMANN, M.D., Chicago.

INHERITANCE OF ANATOMIC DEFECTS

To the Editor:—Anent the question of inheritance of anatomic defects, I suppose that we must go as far back as Sir Oliver Lodge, who said that when an organism is developed it proceeds to run down like a clock as its fund or protoplasmic energy is expended. He referred to species. Weismann is not commonly quoted as reporting lamarckian ideas, but the tendency toward degeneration may be passed on nevertheless. In a case in which a fortune depended on the bearing of a son, I operated on a patient in search for causes of sterility and found closed oviducts as a congenital condition. On one side I folded up the oviduct so that the fimbriated end split open longitudinally could be grafted on a part of an opened oviduct in or part of the lumen near the uterus. This was a success as far as securing pregnancy was concerned, but when the child was born its esophagus opened into the trachea. When nature plans degeneration of a strain, persistence of the tendency may remain if not transmission of a particular form of degeneration.

ROBERT T. MORRIS, M.D., Stamford, Conn.

AIR EMBOLISM

To the Editor:—In THE JOURNAL of February 24 Dr. H. M. Weyrauch Jr. and Drs. F. B. Walsh and H. K. Goldberg report instances of air embolism which were not immediately fatal. It is precisely in these circumstances that the inhalation of 100 per cent oxygen is indicated for the rapid absorption of the nitrogen blocking the arteries and capillaries. This should serve to restore function more quickly and perhaps avert death. The basis for this view can be found in the literature on the modern treatment of caisson disease and in the following articles:

- Fine, Jacob; Frehling, Stanley, and Starr, Arnold: Experimental Observations on Effect of 95 per Cent Oxygen on Absorption of Air from Body Tissues, *J. Thoracic Surg.* 4: 635 (Aug.) 1935.
Schwab, R. S.; Fine, Jacob, and Mixer, W. J.: Reduction of Post-encephalographic Symptoms by Inhalation of 95 per Cent Oxygen, *Arch. Neurol. & Psychiat.* 27: 1271 (June) 1937.
Fine, Jacob; Hermanson, Louis, and Frehling, Stanley: Further Clinical Experiences with 95 per Cent Oxygen for Absorption of Air from Body Tissues, *Ann. Surg.* 107: 1 (Jan.) 1938.

JACOB FINE, M.D., Boston.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

HAZARDS FROM COMPETITIVE SPORTS

To the Editor:—How many deaths and how many serious injuries occur annually in connection with high school football games, and how many in connection with college football games? How do these fatal and non-fatal accident rates in football compare with corresponding rates in other popular games, such as baseball; and how with allegedly dangerous sports, such as sail plane gliding? (Figures for the last point presumably are to be found in German sport or military medical publications.) Comparison with other fighting games, such as rugby, hockey, ice hockey, polo, soccer and the English football would also be welcome.

M.D., Texas.

ANSWER.—According to statistics for the nine years from 1931 to 1939 compiled by Dr. Floyd R. Eastwood, of Purdue University, there was a total of twenty-six deaths in nine years directly attributable to college football, and of 107 deaths attributable to high school football. The number is steadily diminishing. In 1931 there were eight college deaths, twelve high school; in 1939 three college deaths, seven high school. This gives a 63.6 per cent decrease in the number of fatalities directly associated with football. As the estimated number exposed to football for the nine years was 616,000 high school and 65,690 college players, this gives an incidence of deaths per hundred thousand of 1.86 and 4.37 respectively. The motor vehicle rate is 32.8 per hundred thousand for the same age group.

The injuries in high school football were 90.3 per thousand in 1935 (Eastwood).

In a review of a five year period from 1930 to 1934 at Northwestern University by Dr. Marcus H. Hobart there were 368 football injuries, seventy wrestling, fifty basketball, thirty-five baseball and thirty track. As nearly five or six times as many play football, the percentage of danger is about the same as in other sports. These statistics probably give an indication of the general average.

Statistics for allegedly dangerous sports as sail plane gliding as "presumably found in German sport or military medical publications" were not found, nor were those of rugby, hockey, soccer and English football.

LARGE CODEINE DOSAGE

To the Editor:—Would 1 grain (0.065 Gm.) of codeine sulfate every half hour for eight consecutive doses (8 grains [0.5 Gm.] in four hours) be considered a lethal dose for an average normal woman? What is considered a minimal lethal dose of codeine for an adult, if there is any such thing? I am not including drug addicts or people who have been in the habit of taking narcotics of any kind for some length of time. If a person had taken an overdose of codeine, sufficient to cause death, what would the autopsy show? In a case of this kind, on receipt of such a prescription, what is the medicolegal responsibility of the pharmacist to the physician and to the patient?

M.D., Ohio.

ANSWER.—This dosage of codeine sulfate would not be considered lethal for an average normal woman; a fatal result would be exceptional; indeed, a fairly comprehensive search of reference books fails to reveal any reports of fatal codeine poisoning. Flury and Zangger (*Lehrbuch der Toxikologie*, Berlin, Julius Springer, 1928, p. 282) state that doses up to 1 Gm. cause inconvenience rather than danger to life. S. Weir Mitchell took 5 grains (0.32 Gm.) without alarming symptoms (Wood, H. C.: *Therapeutics: Its Principles and Practice*, ed. 11, Philadelphia, J. B. Lippincott Company, 1902, p. 137). The British Pharmaceutical Codex states that "large doses are sometimes given, up to 3 decigrams [5 grains] three times daily." However, the symptoms may be fairly alarming: Lewin (*Gifte und Vergiftungen*, Berlin, Georg Stille, 1929, p. 632) cites a case in which "0.8 Gm. resulted in muscular weakness, miosis, vertigo, mild delirium, clonic spasms, fast pulse, then collapse." In another case, cited by Kobert (*Intoxikationen*, Stuttgart, Ferdinand Enke, 1906, p. 999), 0.5 Gm. (8 grains) produced restlessness, reddening of the skin and conjunctivas, mild muscle twitchings, slowed pulse, slow respiration and widely dilated pupils. Recovery resulted after artificial respiration, gastric lavage and analeptics. The mydriasis persisted for several days. Necropsy would presumably show asphyxia. When the dose is unusually large it would be advisable for the pharmacist to check with the physician before delivering the prescription.

VOLUME 114
NUMBER 21

BLOOD AND ALBUMIN IN URINE

To the Editor:—Does the occurrence of albumin in a specimen of urine in which blood is found present have any significance as to whether the bleeding is from a surgical lesion in the urinary tract or from a so-called medical nephritis? If it has such significance is there any absolutely positive method of determining whether the albumin is coming from a nephritic process or is merely accompanying the surgical bleeding?

U. S. Hargrove, M.D., Baton Rouge, La.

Hematuria protein is practically always present in the urine. Hence the occurrence of proteinuria does not furnish evidence of renal disease. It is therefore of no value in distinguishing between medical and surgical nephritis. The presence of hematuria in the urine may indicate a surgical lesion of the urinary tract. It may also indicate a medical nephritis. The presence of albumin in the urine may indicate a medical nephritis. It may also indicate a surgical lesion of the urinary tract. The presence of albumin in the urine may indicate a medical nephritis. It may also indicate a surgical lesion of the urinary tract.

U. S. Hargrove, M.D., Baton Rouge, La.

ANSWER.—Plasma protein is practically always present in urine containing blood. Hence the occurrence of proteinuria cannot by itself be used to distinguish between medical and surgical diseases of the kidney or lower urinary tract. It is only in case of slight microscopic hematuria due to urinary calculus or other surgical lesions that the ordinary clinical tests for albuminuria may yield a negative result. Under these circumstances persistent slight hematuria without proteinuria speaks strongly against the common medical diseases of the kidney but does not indicate the precise source of the bleeding in the urinary tract.

However, the quantity of protein in the urine is an important factor in the diagnosis. A concentration of 0.2 per cent in ordinary surgical lesions of the kidney reaches a value of 0.4 in the urine of a patient who is dealing with a nephritic process.

in cases of albuminuria or other such conditions. The presence of hematuria in the urine, especially if it is persistent, is a strong indication of a disease of the kidney, but does not indicate the precise source of the blood in the urinary tract.

However, the quantity of protein in the urine is an important aid in differential diagnosis. A concentration of 0.2 per cent of protein (by weight) in urine containing little or no gross blood rarely occurs in the ordinary surgical lesions of the urinary tract. When the proteinuria reaches a value of 0.4 or 0.5 per cent the probability is strong that one is dealing with some diffuse renal process or severe circulatory disturbance. In the presence of gross hematuria the protein estimation should be made on the supernatant protein of the centrifuged urine. A little calculation would show that considerable hemorrhage into the urinary tract is required to raise the concentration of plasma protein in the urine to 0.3 or 0.4 per cent. On the other hand, a slight leakage of protein into each or most of the glomeruli capsules can readily result in several grams of protein in the twenty-four hour urine, because of the great number of glomeruli and the inability of the tubules to reabsorb the large protein molecules. Therefore much albuminuria may be present with little or no demonstrable hematuria in diffuse medical lesions of the kidney. Even in focal nephritis there is usually more protein in the urine than one would expect from the amount of blood found. Occasionally, in the subsidence of acute glomerulonephritis, microscopic hematuria may be observed without proteinuria.

While there is no single absolutely positive method of differentiating between the albuminurias of medical and surgical renal disease, the presence of erythrocytes and other elements in the urine, especially at the level of renal function as indicated by the creatinine clearance, should make it possible to differentiate between the two types of disease in nearly all cases.

While there is no single absolutely positive method of differentiating between the albuminurias of medical and surgical renal processes, the symptoms, the presence of erythrocytes and other casts in the urinary sediment, the level of renal function and the results of cystoscopy or pyelography should make it possible for the physician to arrive at an accurate diagnosis in nearly all cases.

DIABETES AND HYPERTENSIVE DISEASE

DIABETES AND HYPERTENSIVE DISEASE

The Editor:—A man aged 32, weighing 185 pounds (84 Kg.), 5 feet 10 inches (178 cm.) in height, working underground as a miner, during the past two months noticed that his weight was going up, that his face was becoming bloated and red, that his appetite was tremendous, that thirst was considerable and that he urinated abnormally large amounts of water, especially at night. The last few weeks he has noticed a giddiness and slight headache and weakness. He was large and flabby looking, red faced and puffy around the eyes, the heart was slightly enlarged to the left, there were several decayed teeth. Urinalysis revealed a glucose reaction, the pulse was rapid (90) the blood pressure was 200 systolic, 130 diastolic, and the patellar reflexes were absent. Urinary negative, twenty-four hour samples of urine ranging from 1,014 to 1,020, albumin granular test plus casts, a few red cells and no bacteria. The dextrose tolerance test was fasting 80 mg., first hour 121 mg., second hour 146 mg. and third hour 130 mg. This week. Blood urea nitrogen was 12 mg., blood urea nitrogen 130 mg. Repeated blood counts did not reveal anemia, leukocytosis or any other abnormality. The blood Wassermann reaction was negative. A tentative diagnosis of mild diabetes complicated by a nonspecific chronic nephritis and a moderate amount of insulin put on a modified diabetic-nephritic diet of 2,500 calories at bed rest with a limitation of sugars and a moderate amount of protein. The bad teeth were removed, a preparation of theobromine and phenobarbital and erythrol tetranitrate were used as drugs, and moderate amounts of insulin (20 units daily in divided doses with poor tolerance and a slight reaction) but the patient does not seem to improve and the blood pressure is going up. Is the diagnosis correct? Can you suggest further treatment? Can chronic nephritis spill as much as 20 to 30 Gm. of dextrose in twenty-four hours in the urine? The symptoms at first suggested purely a diabetic condition but the signs tend more to a nonspecific chronic nephritis. Incidentally the patient's temperature has always remained normal. He still has the symptoms of polyuria, polydipsia and polyphagia. M.D., Idaho.

There would seem to be nothing amiss with the case. The clinical symptoms are clearly warrant such a diagnosis. Diabetes, although rare among miners, is not infrequently associated with hypertension, and the results of cystoscopy may lead the physician to arrive at an incorrect conclusion.

ANSWER.—There would seem to be nothing amiss with the diagnosis of diabetes in this case. The clinical symptoms and the laboratory observations clearly warrant such a diagnosis. The dextrose tolerance curve is that of diabetes, although not severe. The occurrence of a blood pressure of 200/130 in a 32 year old man is not part of diabetes. This indicates the additional presence of hypertensive disease. The evidence of nephritis

MINOR NOTES

is not good, as cylindruria and hematuria are not infrequently encountered in diabetes. In order to clear up some obscurities in this case one must determine whether any feature of the hypertensive disease might produce glycosuria. First one must consider the possibility of a cerebral hemorrhage in the region of the fourth ventricle. This seems unlikely, as other signs of cerebral hemorrhage are lacking and this glycosuria is persistent. Second, one must consider the presence of an adrenal tumor. Certain adrenal tumors could produce both hypertension and glycosuria. These are rare but certain features of this case arouse suspicion. The easily controlled but persistent hyperglycemia, the rising blood pressure and the hematuria are suggestive circumstances. Such a diagnosis is not easy to confirm. X-ray examination will sometimes reveal the tumor. Pyelograms are sometimes helpful and occasionally the tumors may be palpated.

If these possibilities fail of proof, it would seem wise to treat with hypotensive with mild diabetes and not treat the hypertension with insulin.

DEATH

If these possibilities fail of proof, it would seem wise to treat the patient as hypertensive with mild diabetes and not treat the diabetes too vigorously with insulin.

PINWORMS, HEXYLRESORCINOL AND DEATH

PINWORMS, HEXYLRESORCINOL AND DEATH

To the Editor:—A normal boy aged 4 years in good health had pinworms. Having had no breakfast, at 9 a. m. he received 0.4 Gm. of hexylresorcinol (capriokol). A cleansing soap-suds enema was given and returned with good results. At 10:15 1 pint of hexylresorcinol solution (1:1,000) with 8 ounces of warm water was expelled. At 10:30 the boy complained of epigastric cramps and headache, which quickly became severe. The child was brought up remains of the medication. Coma and convulsions appeared, which seemed to affect the left side of the body more. The temperature immediately hospitalized. On admission he was comatose and was 97 F., frequent severe convulsions of all extremities. The pupils were widely dilated and respiratory rate 10, pulse rate 120. The right was larger than the left. Both optic disks were blurred. No neck rigidity or Brudzinski sign was present. The adenopathy was present. The abdomen was distended moderately. The right Babinski sign was extensor. There were no other positive neurologic phenomena. The blood count on admission was 5,400,000 red blood cells, 12 per cent lymphocytes and 4 per cent polymorphonuclears, no eosinophils, was not done, but no abnormally early polymorphonuclears, no eosinophils, spinal fluid normal and clear. The urine was not obtained. Phenobarbital was given hypodermically, ether to control convulsions, bromide and chloral by rectum. Gastric lavage was done and magnesium sulfate was passed through a stomach tube. The temperature was 104 F., pulse rate 140, respiration rapid and irregular. The coma was not as deep and the boy was tossing himself around the bed. The pupils were still dilated and the disks blurred. This condition continued until 6 o'clock (eight hours from the onset of symptoms), when the patient vomited blood and passed some blood rectally, developed pulmonary edema and died. Autopsy showed cerebral edema, slight congestion of the mucous membranes of the stomach and upper small intestine and renal congestion. Could you assist me in the solution of the following before? Have cases of severe hexylresorcinol poisoning been reported before? What clinical pictures have they presented in the mild and severe forms? How could one have tested sensitivity before treatment? Can hexylresorcinol decompose to form a poisonous by-product? Does the white count of 105,000 point to a sensitivity reaction even though there is absence of eosinophilia? M.D., N. Y.

In answering this inquiry regarding death following hexylresorcinol in a case of pinworm infestation the signs and symptoms observed are slowly absorbed, a No record

ANSWER.—In answering this inquiry regarding death following the use of hexylresorcinol in a case of pinworm infestation, it is impossible to account for the signs and symptoms observed. Hexylresorcinol is a local irritant, it is slowly absorbed, and about 20 per cent of it is excreted in the urine. No record has been found of systemic poisoning from hexylresorcinol in spite of its having been given in large amounts to many thousands of persons. One would not believe that the child could have died from a gastrointestinal hemorrhage; neither could the child have died from decomposition of hexylresorcinol after oral administration as practically all of the hexylresorcinol after oral administration has been accounted for by finding it in the urine and stools. The lower members of any series of phenols may cause convulsions after absorption, but these are not seen with hexylresorcinol no convulsions were seen. The dose of hexylresorcinol given to the child is a common therapeutic dose. There is nothing in this case which would indicate intoxication from hexylresorcinol.

The description is read "1 pint of hexylresorcinol solution and 8 ounces of warm water was given as an enema." The solution was the commercial S. T. 3rd approximately 150 cc. of glycerol from local irritation a few

As the description is read "1 pint of hexylresorcinol solution (1:1,000) with 8 ounces of warm water was given as an enema." If this hexylresorcinol solution was the commercial S. T. 37, this would have contained approximately 150 cc. of glycerin, which well might have caused collapse from local irritation and removal of water, but even this could not account for the fever, white count and convulsions, except that it is well known among pediatricians that any severe poisoning may show a remarkable symptom complex in children.

The cause of death of this child remains unexplained.

PERSISTENT INTERCOSTAL NEURALGIA

To the Editor:—A woman aged 59 has had neuralgia involving the left fifth, sixth, seventh and eighth intercostal nerves since Aug. 6, 1937, at which time the pain set in suddenly. The red and white blood cells and the hemoglobin are normal. The blood Wassermann reaction is negative. Physical examination is entirely negative except for the specified nerves. The patient has received two nerve blocks of the involved nerves with no result. She has also received roentgen therapy, sinusoidal current, thiamin chloride and short wave therapy, without good results. She has had to take from four to six capsules daily containing morphine sulfate or pantopon or dilaudid, plus acetylsalicylic acid, in spite of which it has been necessary to give her from one-fourth to one-half grain morphine sulfate hypodermically two or three times a week. She has not been free from pain since the onset for longer than four days at a time. Two neurosurgeons have felt that direct attack on the involved nerves is indicated. Is there anything else I can offer the patient before subjecting her to this formidable step? Leon A. Frankel, M.D., Philadelphia.

ANSWER.—Neuralgia of the type described is often perplexing to treat; drug treatment usually is ineffective and a large number of such patients eventually seek surgical relief from both the pain and the heavy doses of drugs. Without some such treatment which will, by anatomic interruption, abolish the pain unquestionably, the disturbance may continue unabated for an indefinite time and, since no specific lesion exists, any attempt at direct therapy, other than surgical, is usually futile.

Following the suggestions of Leriche, a procainization of the sympathetic ganglion of the corresponding segments might be attempted. This is a procedure requiring much skill, and an inaccurate injection frequently leads to the opinion that such treatment is without merit. Such an injection failing, and considering the treatments already tried, posterior rhizotomy, sympathetic ramisectomy or even chordotomy (low cervical or high thoracic in this case) are the three surgical measures of most promise. Of these three, chordotomy is the only one which need be considered a "formidable step," and it can be safely done by an experienced neurosurgeon.

INTESTINAL ADHESIONS AND PAIN

To the Editor:—A young married woman has had four laparotomies, the last one a sympathectomy for severe dysmenorrhea. She is now suffering from severe attacks of abdominal pain resulting from what appear to be numerous intestinal adhesions. What form of therapy do you suggest for treating the adhesions and the attacks of pain? M.D., New Jersey.

ANSWER.—This is a difficult problem. One must first be certain that all other causes of abdominal pain have been excluded before the diagnosis of intestinal adhesions is made. The urinary tract should be carefully studied as well as the gallbladder, stomach and duodenum. Diaphragmatic hernia should be excluded. If it seems that intestinal adhesions most likely explain the attacks of pain it would be well to try to take flat x-ray plates of the abdomen in the horizontal and vertical positions to see whether there are single, distended loops. Usually it is unwise to do any operation for adhesions unless frank intestinal obstruction occurs. Occasionally, however, if there is a definite inflated loop which can be identified by x-ray examination at the time of the maximum pain, a minimal type of operation to free the offending adhesions may be of value. In this event it is worth trying to use some amniotic fluid concentrate after the operation.

If operation is not carried out and the pain persists, a mild sedation must be given. It is desirable to avoid narcotics because of the habit-forming tendency.

Finally, one should be sure there is not an improper evaluation of pain because of psychiatric disturbance.

REACTIONS FROM SOLUTIONS USED FOR OBLITERATING VEINS

To the Editor:—I am eager to know whether there is any medical literature supporting the conclusion that erythema multiforme may be caused by the various or any specific chemical used in the injection treatment of hemorrhoids. Guthrie H. Wisener, M.D., Richmond, Ind.

ANSWER.—Sensitization to solutions used for obliterating veins has been observed repeatedly. Apparently Ritchie (*Edinburgh M. J.*, November 1933, p. 157) was the first to call attention to these reactions. He described the following three types: (1) erythematous patches on the skin, (2) gastrointestinal disturbances with abdominal pain and diarrhea appearing shortly after the injections, and (3) pain across the back followed by collapse, cyanosis, fall in blood pressure and temporary loss of consciousness. This severe "nitritoid" reaction may closely resemble pulmonary embolism. The erythematous patches are the most frequent type of sensitization and have been seen after

the use of quinine, salicylates and sodium morrhuate and even after solutions of sugar if they contain nitrogenous impurities. A partial list of references may be consulted:

PSYCHIATRY

To the Editor:—Does psychiatry include the study of criminal psychology, child psychology, correction of wayward adolescence and sexual disturbances besides the study of the insane? How can an individual obtain adequate training in these branches and what are the future possibilities of these branches in the medical field? Will a residency in a state institution give an individual sufficient background to carry on such studies?

M. S. Dudich, M.D., East Bangor, Pa.

ANSWER.—The field of psychiatry should include the study of criminal psychology, the psychology of children, the correction for boys of the wayward adolescence, disturbances of the function of sex and, further, the study of the insane.

Adequate training in these branches should include internal medicine, neurology and psychiatry. To be a psychiatrist of merit requires more than an internship in a state hospital.

The future possibilities in psychiatry are similar to those which existed in surgery when Lister made his first antiseptic spray.

ANIRIDIA

To the Editor:—A white girl baby aged 6 months was brought to me because the mother did not think the child could focus her eyes. The baby is perfectly normal in every respect except for the eyes, the rudimentary iris being represented by a thin black line around the edge of the cornea. There are no corneal opacities and both retinas appear normal. I have been able to find but little in any of my books on aniridia. Please let me know the relative frequency of this condition, the treatment, and the prognosis as to useful eyes in this patient. Any information relative to this condition will be appreciated.

W. Hill McCaslan, M.D., Union Springs, Ala.

ANSWER.—There is an extensive literature dealing with aniridia. It is discussed in the second volume of the *Textbook of Ophthalmology* by Duke-Elder, 1938, page 1298. Other references, possibly not so comprehensive, are to the *Kurzes Handbuch der Ophthalmologie*, by Seefelder, volume 1, page 562; and the *Eye and Its Diseases*, by Berens, 1936, page 624.

OVERWEIGHT YOUNG GIRL

To the Editor:—A 9 year old girl was brought to me because of overweight and oversize. Her history and examination are negative except for obesity and dorsal padding of the fingers. The basal metabolic rate taken last year was normal. Her height is 57½ inches (146 cm.) and weight 123¼ pounds (56 Kg.). My diagnosis is prepubertal pituitary obesity. My plan is to give her small doses of thyroid daily and injections of solution of posterior pituitary biweekly. My questions are: Are there any better pituitary extracts for this purpose now on the market? Is twice a week often enough to give the injections or should they be given daily? Norman P. Rindge, M.D., Clinton, Conn.

ANSWER.—The most important therapeutic procedure is the administration of a well balanced weight reducing diet. This should be adequate in everything except calories. It may be supplemented with small doses of desiccated thyroid (as much as 1 grain [0.06 Gm.] of the U. S. P. material daily), but the main problem is dietary. There is no good evidence that solution of posterior pituitary is of value in the treatment of obesity. Moreover, there is no extract of the anterior lobe of the pituitary that is effective in this disorder.

HOLLYHOCK POLLEN INSECT POLLINATED

To the Editor:—Please state specifically whether hollyhock pollen is wind borne or insect borne. I do not find a specific statement about this matter in any book on allergy at my disposal, although the general statement is made that the usual garden flowers produce insect borne pollen, listing rose, sunflower, cosmos, aster, dandelion and goldenrod. M.D., Kentucky.

ANSWER.—Not only hollyhock but all members of the mallow family are strictly insect pollinated. A reference to three members of this family in the genus *Hibiscus* will be found on page 181 of Scheppegrell's "Asthma and Hay Fever," Philadelphia, Lea & Febiger, 1922.

Medical Examinations and Licensure

COMING EXAMINATIONS

NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, May 18, page 2052.

STATE AND TERRITORIAL BOARDS

ALABAMA: Montgomery, June 18-20. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ALASKA: Juneau, Sept. 3. Sec., Dr. W. W. Council, Box 561, Juneau.

ARIZONA: *Basic Science*. Tucson, June 18. Sec., Dr. Robert L. Nugent, University of Arizona, Science Hall, Tucson. *Medical*. Phoenix, July 2-3. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

ARKANSAS: *Medical (Regular)*. Little Rock, June 6-7. Sec., Dr. D. L. Owens, Harrison. *Medical (Eclectic)*. Little Rock, June 6-7. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.

CALIFORNIA: *Oral examination* (required when reciprocity application is based on a state certificate or license issued ten or more years before filing application in California), Los Angeles, July 15. *Written examination*. San Francisco, June 24-27. Sec., Dr. Charles B. Pinkham, 1020 N St., Sacramento.

COLORADO: *Basic Science*. Denver, May 28-29. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver. *Medical*. Denver, July 2-6. *Applications must be on file not later than June 17*. Sec., Dr. Harvey W. Snyder, 831 Republic Bldg., Denver.

CONNECTICUT: *Basic Science*. New Haven, June 8. Chairman State Board of Healing Arts, Dr. Charles M. Bakewell, 1895 Yale Station, New Haven. *Medical. Written*. Hartford, July 9-10. *Endorsement*. Hartford, July 23. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. *Homeopathic*. Derby, July 9-10. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

DELAWARE: *Examination*. Dover, July 9-11. *Reciprocity*. Dover, July 16. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA: *Basic Science*. Washington, Oct. 21-22. Sec., Dr. George C. Ruhland, 203 District Bldg., Washington.

FLORIDA: Tampa, June 17-18. Sec., Dr. William M. Rowlett, Box 786, Tampa.

GEORGIA: Atlanta, June. *Joint-Sec.*, Mr. R. C. Coleman, 111 State Capitol, Atlanta.

IDAHO: Boise, Oct. 1. Dir., Bureau of Occupational License, Mr. H. B. Whittlesey, 355 State Capitol Bldg., Boise.

ILLINOIS: Chicago, June 25-27. Acting Superintendent of Registration, Mr. Lucien A. File, Springfield.

INDIANA: Indianapolis, June 18-20. Sec., Board of Medical Registration and Examination, Dr. J. W. Bowers, 301 State House, Indianapolis.

IOWA: *Medical*. Iowa City, June 4-6. *Basic Science*. Des Moines, July 9. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines.

KANSAS: Kansas City, June 18-19. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. Seventh St., Kansas City.

KENTUCKY: Louisville, June 6-8. Sec., Dr. A. T. McCormack, 620 S. Third St., Louisville.

MAINE: Augusta, July 2-3. Sec., Dr. Adam P. Leighton, 192 State St., Portland.

MARYLAND: *Medical*. Baltimore, June 18-21. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. *Homeopathic*. Baltimore, June 18-19. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: Boston, July 9-11. Sec., Dr. Stephen Rushmore, 413-F State House, Boston.

MICHIGAN: Ann Arbor and Detroit, June 12-14. Sec., Dr. J. Earl McIntyre, 202-4 Hollister Bldg., Lansing.

MINNESOTA: *Basic Science*. Minneapolis, June 4-5. Sec., Dr. J. Charney McKinley, 126 Millard Hall, University of Minnesota, Minneapolis. *Medical*. Minneapolis, June 18-20. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.

MISSISSIPPI: Jackson, June. Asst. Sec., Dr. R. N. Whitfield, Jackson. MISSOURI: St. Louis, June 6-8. Sec., State Board of Health, Dr. Harry F. Parker, State Capitol Bldg., Jefferson City.

MONTANA: *Reciprocity*. Helena, Sept. 30. *Written*. Helena, Oct. 1-2. Sec., Dr. S. A. Cooney, 216 Power Block, Helena.

NEBRASKA: *Medical*. Omaha, June 12-14. *All applications must be on file 15 days prior to date of examination*. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, 1009 State Capitol Bldg., Lincoln.

NEVADA: *Reciprocity with oral examination*. Aug. 5. Sec., Dr. Fred M. Anderson, 215 N. Carson St., Carson City.

NEW JERSEY: Trenton, June 18-19. Sec., Dr. Earl S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: Santa Fe, Oct. 7-8. Sec., Dr. Le Grand Ward, 135 Sena Plaza, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, June 24-27. Chief, Bureau of Professional Examinations, Mr. Herbert J. Hamilton, 315 Education Building, Albany.

NORTH DAKOTA: Grand Forks, July 2-5. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OHIO: Columbus, June 3-6. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

OKLAHOMA: Oklahoma City, June 5-6. Sec., Dr. James D. Osborn Jr., Frederick.

OREGON: *Medical*. Portland, June 18-20. Sec., Dr. Joseph F. Wood, 509 Selling Bldg., Portland. *Basic Science*. July 6. Sec., State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

PENNSYLVANIA: *Written*. Philadelphia and Pittsburgh, July 9-11. *Bed-side*. Philadelphia, July 12-13. Dir., Bureau of Professional Licensing, Dr. James A. Newpher, 353 Education Bldg., Harrisburg.

PUERTO RICO: San Juan, Sept. 3. Sec., Dr. O. Costa Mandry, Box 3854, Santurce.

RHODE ISLAND: Providence, July 11-12. Sec., Division of Examination, Dr. Robert M. Lord, 366 State Office Bldg., Providence.

SOUTH CAROLINA: Columbia, June 25. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

SOUTH DAKOTA: Rapid City, July 16-17. Dir., Medical Licensure, Dr. J. F. D. Cook, Pierre.

TENNESSEE: Knoxville, Memphis and Nashville, June 14-15. Sec., Dr. H. W. Qualls, 130 Madison Ave., Memphis.

TEXAS: San Antonio, June 17-19. Sec., Dr. T. J. Crowe, 918-20 Mercantile Bldg., Dallas.

VERMONT: Burlington, June 11-13. Sec., Dr. W. Scott Nay, Underhill.

VIRGINIA: Richmond, June 18-20. Sec., Dr. J. W. Preston, 30½ Franklin Rd., Roanoke.

WASHINGTON: *Basic Science*. Seattle, July 11-12. *Medical*. Seattle, July 15-17. Sec., Department of Licenses, Mr. Nelson N. Vaughn, Olympia.

WEST VIRGINIA: Huntington, July 1-3. Sec., Public Health Council, Dr. Arthur E. McClue, State Capitol, Charleston.

WISCONSIN: *Basic Science*. Milwaukee, June 1. Sec., Prof. Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee. *Medical*. Milwaukee, June 25-28. Sec., Dr. E. C. Murphy, 314 E. Grand Ave., Eau Claire.

WYOMING: June 3-4. Sec., Dr. M. C. Keith, Capitol Bldg., Cheyenne.

Wyoming February Report

Dr. M. C. Keith, secretary, Wyoming State Board of Medical Examiners, reports the written examination held at Cheyenne, Feb. 14, 1940. The examination covered twelve subjects and included eighty-two questions. An average of 75 per cent was required to pass. Four candidates were examined, all of whom passed. One physician was licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Loyola University School of Medicine.....	(1939)*		79.2
Creighton University School of Medicine.....	(1933)		79.1
University of Nebraska College of Medicine.....	(1938)		77.6
Jefferson Medical College of Philadelphia.....	(1938)		78.5

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois.....	(1905)		Illinois

* This applicant has completed four years' medical work and will receive the M.D. degree on completion of internship. License has not been issued.

North Dakota January Report

Dr. G. M. Williamson, secretary, North Dakota State Board of Medical Examiners, reports the written examination held at Grand Forks, Jan. 2-5, 1940. The examination covered thirteen subjects and included 100 questions. An average of 75 per cent was required to pass. Eight candidates were examined, all of whom passed. Two physicians were licensed by reciprocity. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Northwestern University Medical School.....	(1938)		79.6
Rush Medical College.....	(1937)		84.7
Univ. of Minnesota Med. School (1924) 85, (1929) 80.5, (1939) 80.4	(1936)		80.4
University of Pennsylvania School of Medicine.....	(1936)		81

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Rush Medical College.....	(1914)		Illinois
Creighton University School of Medicine.....	(1921)		S. Dakota

Vermont February Examination

Dr. W. Scott Nay, secretary, Vermont State Board of Medical Registration, reports the written examination held at Burlington, Feb. 13-15, 1940. The examination covered twelve subjects and included ninety questions. An average of 75 per cent was required to pass. Four candidates were examined, three of whom passed and one failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Cornell University Medical College.....	(1938)*		86.7
University of Vermont College of Medicine.....	(1939)*		86.2
Medizinische Fakultät der Universität, Wien.....	(1920)*		86.3

School	FAILED	Year Grad.	Number Failed
Universidad Central de España Facultad de Medicina, Madrid.....	(1933)		1

* Licenses have not been issued.

certain factual errors. Thus Ampère is again stated to have been a Swedish physicist, when his French nationality is common knowledge. The book is divided into six chapters, the first two offering in abbreviated and elementary form the physical and physiologic fundamentals of infra-red radiation. The remainder is devoted to a description of popular apparatus, the technic and the treatment of some common symptoms and disorders, and concludes with a tabulation of the results of treatment in more than 1,000 cases. At the outset the author has taken the laudable attitude of warning against regarding this method as a panacea and of ascribing to it on the basis of his clinical experience the role of a useful adjuvant.

Lee on the Levee: An Historical Novel. By Ralph Cannon. Cloth. Price, \$2.50. Pp. 188. New York: Saravan House, 1940.

Robert E. Lee as a young lieutenant in the engineering corps of the United States Army was ordered to St. Louis in 1837 to supervise work on the Mississippi River which would deepen the channel at St. Louis. During a part of this period of service, Lee's family and Dr. William Beaumont's family both lived in the mansion of Governor William Clark on the water front. The author has made a delightful story out of the association of these two famous families at that time, which gives a glimpse into the social life, the efficient and methodical ways in which Lieutenant Lee conducted his engineering work, and a brief account of the renowned physiologic experiments of Dr. Beaumont. The Canadian voyageur Alexis St. Martin is said to have lived with Dr. Beaumont and performed the duties of acting as servant at some of the social occasions described. The basis of the story is a collection of unpublished letters from the Lee family to the Beaumont family written after Lieutenant Lee had been ordered elsewhere. These letters were obtained for the author by Dr. Arno B. Luckhardt, professor of physiology at the University of Chicago, who obtained them for a museum display from Ethan Allen Beaumont of Green Bay, Wis., a grandson of Dr. Beaumont. Unfortunately the replies of the Beaumonts to the Lee letters have not been found. The author suggests that they may have been ransacked while the army was occupying Arlington, Lee's home in Virginia, just across the river from Washington, during the Civil War. The story serves also to show the admirable qualities in Lee as a young man, qualities of which the entire world learned later in Lee's life.

Accepted Dental Remedies Containing a List of Official Drugs Selected to Promote a Rational Dental Materia Medica and Descriptions of Acceptable Nonofficial Articles 1939. Council on Dental Therapeutics. Cloth. Price, \$1. Pp. 304. Chicago: American Dental Association, 1939.

This valuable compendium is frankly modeled on New and Nonofficial Remedies and Useful Drugs of the Council on Pharmacy and Chemistry of the American Medical Association, which are, of course, much older than the dental publication. The book is in handy pocket size and is competently indexed. The products included are classified and grouped according to chemical composition or therapeutic use. At the head of each grouping appears a compendious general statement bringing out the characteristics of the preparations which are of interest and usefulness to the dentist. The same purpose is excellently carried out in the brief statement of actions and uses under each different drug. For example, under Calcium Compounds there is given a concise statement of present day knowledge on the use of calcium preparations as aids to proper calcification, possible prevention of caries, and the relationship of vitamin D and parathyroid. Under the various calcium compounds included appear terse indications for dental therapeutic use and technical specifications for those which may be used as abrasives in dentifrices. Under dentifrices are listed some fifty commercial brands of dental pastes, powders and creams. This is a marked increase over the number listed in former editions. It must be concluded therefore that the work of the Council on Dental Therapeutics is bearing fruit and that commercial houses in increasing numbers are making their preparations and claims in accordance with the council's rational and enlightened rules. It is to be hoped that the dental profession will continue increasingly to support the work of their council in this and other respects.

The book contains an excellent outline on symptoms and treatment of acute poisoning; useful tables of solubilities, weights and measures; a brief but comprehensive therapeutic index, with a suggestive and rather extensive set of formulas utilizing the drugs described in the book. A complete bibliographic index to reports on articles found unacceptable by the council completes a handbook that should be the vade mecum of every practicing dentist and dental student.

Frontier Doctor. By Urling C. Coe, M.D. Cloth. Price, \$2.50. Pp. 264. New York: Macmillan Company, 1939.

A young medical graduate arrived in Bend, Oregon, in 1905 ready to begin practice in a new pioneer town a hundred miles from a railroad. He spent the night in a room shared with five other men and dressed next morning in freezing cold surrounded by a virgin pine forest which extended westward mile after mile to snow covered mountains. Here in the heart of the last pioneer stock country of the West the author remained for many years practicing among cowboys, sheepmen, Indians and other hardy folk. His book of experiences in this wide open town is an exciting tale, well written. He delivered babies, fought epidemics and treated those wounded in rough and tumble fights among Indians, horse thieves and rustlers. He pictures some of the personalities in this community. Finally for nine years he was associated here in practice with a schoolmate from a Chicago school. One may spend pleasantly an afternoon or evening reading this interesting story.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Liability of Hospital and Medical Staff for Nonunion of Fracture of Femur.—The Security Benefit Association, an incorporated fraternal insurance association, maintained for the use of its members a hospital separately incorporated as the "Security Benefit Home and Hospital Association." The plaintiff, a 56 year old woman, a member of the fraternal association and entitled to hospital benefits, was admitted to the hospital in April 1933 for a series of operations including a cholecystectomy, the removal of bunions and resection of her coccyx. She was attended by Dr. Hiebert and other physicians, all of whom were employed by the hospital on a salary basis as resident physicians and not as independent practitioners. May 10, two days after the last operation, the patient fell out of bed and sustained a subcapital fracture through the neck of her left femur. Because her operative wounds had not yet healed, treatment of the fracture was complicated. The fracture was reduced and immobilization instituted by a particular type of plaster cast, variously described as a "well leg traction splint" or "Jones Modified Traction cast," apparently the Jones method of incorporating a screw traction apparatus in plaster boots enclosing both the injured and the well leg from the knees to the toes. She contracted boils and suffered great pain in her back in the region of the operative wound for the removal of her coccyx, which wound discharged pus. After taking check-up roentgenograms the plaster cast was removed by Dr. Hiebert on June 12, four weeks and five days after the reduction of the fracture. About seventy diathermy treatments were administered by one Musick, a hospital attendant who was neither a physician nor a nurse. Nonunion of the fracture resulted. The patient was discharged from the hospital Sept. 22, 1933. During the next five months she underwent treatments from a half dozen physicians, not connected with the hospital, designed to build up her strength. A Whitman's reconstruction operation was performed on her left hip in February 1934.

The patient brought suit for malpractice, Sept. 20, 1935, and recovered judgment against the fraternal association, the hospital and Dr. Hiebert on a finding of the jury that: (1) she had sustained injuries due to unskillful treatment or lack

Further, the court could not agree with a contention of the patient that the defendants, on learning that union was not taking place, should have instituted other treatment to induce union instead of concealing from the patient her true condition and the urgency for other treatment. Neither, in the opinion of the court, was it shown that the defendants failed to treat the patient with that degree of care and skill prevalent among hospitals and physicians in that vicinity, nor that a proper degree of care and skill would have caused the fracture to unite within a short time. Medical testimony was in accord that failure to obtain bony union in fractures of the neck of the femur is common particularly in patients of the plaintiff's age, where failure is estimated as occurring in from 35 to 50 per cent of the cases. It was not shown that some treatment other than that which the patient received would have been proper or advisable. The evidence did show that because of her physical condition the patient was unable to undergo some other treatments commonly used to induce union when the original treatment has failed. The jury's finding that when the cast was removed the patient was not suffering from "any ailment other than the fracture of the femur and the previous operations" was not supported by the evidence. In fact, as already stated, treatments to build up her strength to undergo the Whitman's reconstruction operation were necessary. Furthermore, stated the court, "there was no evidence that it was unprofessional, negligent or wrongful in this case (or in any case) for a physician to conceal from his patient her condition."

For the reasons stated, the Supreme Court, in effect, instructed the trial court to enter judgment for the defendants.—*Blackburn v. Security Ben. Ass'n et al. (Kan.)*, 86 P. (2d) 536.

COMING MEETINGS

American Medical Association, New York, June 10-14. Dr. Olin W. Wells, 535 N. Dearborn St., Chicago, Secretary.
 American Association for the Surgery of Trauma, Atlantic City, N. J., June 7-8. Dr. Ralph G. Carothers, 409 Broadway, Cincinnati, Secretary.
 American Association for Thoracic Surgery, Cleveland, June 6-8. Dr. Richard H. Meade Jr., 2116 Pine St., Philadelphia, Secretary.
 American Association of Genito-Urinary Surgeons, Skytop, Pa., June 20-22. Dr. Charles C. Higgins, 2020 East 93d St., Cleveland, Secretary.
 American Broncho-Esophagological Association, New York, June 5. Dr. Paul Holinger, 1150 N. State St., Chicago, Secretary.
 American College of Chest Physicians, New York, June 8-10. Dr. Robert B. Homan Jr., P. O. Box 1069, El Paso, Texas, Secretary.
 American College of Radiology, New York, June 12. Mr. M. F. Cahal, 540 North Michigan Bvld., Chicago, Executive Secretary.
 American Dermatological Association, Colorado Springs, Colo., May 30-June 1. Dr. Fred D. Weidman, 36 Hamilton Walk, Philadelphia, Secretary.
 American Gastro-Enterological Association, Atlantic City, N. J., June 10-11. Dr. Albert F. R. Andresen, 88 Sixth Ave., Brooklyn, N. Y., Secretary.
 American Gynecological Society, Quebec, Canada, June 17-19. Dr. Richard W. TeLinde, 11 East Chase St., Baltimore, Secretary.
 American Heart Association, New York, June 7-8. Dr. Howard B. Sprague, 50 West 50th St., New York, Secretary.
 American Laryngological Association, Rye, N. Y., May 27-29. Dr. C. J. Imperatori, 108 East 38th St., New York, Secretary.
 American Laryngological, Rhinological and Otolological Society, New York, June 6-8. Dr. C. Stewart Nash, 277 Alexander St., Rochester, N. Y., Secretary.
 American Medical Women's Association, New York, June 9-10. Dr. Elizabeth Parker, 1835 Eye St., Washington, D. C., Secretary.
 American Neurological Association, Rye, N. Y., June 5-7. Dr. Henry A. Riley, 117 East 72d St., New York, Secretary.
 American Osteopatheal Society, Hot Springs, Va., June 3-5. Dr. Eugene Friesner, New Haven, Conn., Secretary.
 American Y., May 30-31. Dr. Isidore Friesner, Secretary Pro-Tem.
 American Y., York, June 23-28. Mrs. Eloise nd, Secretary.
 American T. Land, Va., June 9-11. Dr. Curtice s, Texas, Secretary.
 American Rosser, June 10-11. Dr. William E. Angeles, Secretary.
 American Costolow, June 10. Dr. Loring T.
 American Rheumatism Association, New York, June 10-11. Dr. Swaim, 372 Marlborough St., Boston, Secretary.
 American Society of Clinical Pathologists, New York, June 6-10. Dr. Alfred S. Giordano, 531 N. Main St., South Bend, Ind., Secretary.
 American Therapeutic Society, New York, June 7-8. Dr. Oscar B. Hunter, 1835 Eye St., N.W., Washington, D. C., Secretary.
 American Urological Association, Buffalo, N. Y., June 24-27. Dr. Clyde L. Deming, 789 Howard Ave., New Haven, Conn., Secretary.
 American Society of Internal Secretions, New York, June 10-11. Westwood Blvd., Los Angeles, Secretary.
 Rangeley Lakes, June 23-25. Dr. F. R. Portland, Secretary.
 Portland, Ore., June 25-27. Miss Anna C. ston, Secretary.
 of, Bozeman, June 18-20. Dr. Thomas F. Building, Great Falls, Secretary.
 Association, New York, June 4-6. Dr. G. 319, 1819 Broadway, New York, Secretary.
 National Tuberculosis Association, Cleveland, June 3-6. Dr. Charles J. Hatfield, 50 West 50th St., New York, Secretary.
 New Jersey Medical Society of Atlantic City, June 4-6. Dr. Alfred Stahl, 53 Lincoln Park, Newark, Secretary.
 New Mexico Medical Society, June 27-30. Dr. L. B. Cohenour, 219 West Central, Secretary.
 Pacific Northwest Medical Assn. June 26-29. Dr. C. W. Countryman, 407 River, Secretary.
 Rhode Island Medical Society, June 26-27. Dr. W. Wells, 124 Waterman St., Providence, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1930 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Public Health, New York

30:219-324 (March) 1940

- Epidemiologic Studies of Tuberculosis. L. L. Lumsden, Nashville, Tenn., and W. P. Dearing, Montgomery, Ala.—p. 219.
Development of Tuberculosis in Controlled Environment. R. E. Plunkett, G. W. Weber, W. Siegal, Albany, N. Y., and Rose R. Donk, Newark, N. Y.—p. 229.
Food Value and Economics of Skim Milk. J. S. Abbott, Washington, D. C.—p. 237.
Application of Phosphatase Test to Butter. E. H. Parfitt, W. H. Brown, Lafayette, Ind., and G. W. Shadwick Jr., Chicago.—p. 240.
Microbiologic Content of Paper Board Used in Packaging of Foods. J. R. Sanborn, Geneva, N. Y.—p. 247.
Microbiology of Paper and Paper Board for Use in Food Industry. F. W. Tanner, Urbana, Ill.; E. Wheaton, Maywood, Ill., and C. O. Ball, New York.—p. 256.
Incidence of Rabies in Dogs and Rats as Determined by Survey. G. A. Denison, Birmingham, Ala., and C. N. Leach, Montgomery, Ala.—p. 267.
Educating Medical Students and Other Groups Concerned with Registration of Vital Statistics Data. I. C. Plummer, Columbus, Ohio.—p. 270.
Needle Puncture Method for Determination of Bacterial Contamination of Paraffined Milk Containers. C. S. Mudge and D. C. Foord, Davis, Calif.—p. 273.
Health Education of the Public. W. F. Higby, San Francisco.—p. 278.

Quartan Malaria for Neurosyphilis Among Negroes.—

Fong presents the results of quartan malarial therapy among 436 Negro neurosyphilitic patients. It is generally accepted that Negroes are particularly immune to the organism of benign tertian malaria and therefore are refractive to this type of malarial therapy. A total of 229, or 53.2 per cent, of the 436 Negro patients responded successfully following malarial inoculation. This is a far greater response than that following tertian malaria, but it is considerably lower than the figures quoted by other authors. Of this number, 13.9 per cent were markedly improved by treatment, 33.1 per cent were improved and 52.8 per cent were unimproved. There were thirty-eight, or 12.2 per cent, deaths in the successfully inoculated group not directly attributable to malaria. Six deaths were due directly to therapeutic quartan malaria. There appeared to be no definite correlation between clinical and serologic improvement and vice versa, with the exception that the majority of patients clinically improved showed concomitant serologic improvement.

Bismuth in Pregnancy and Bones of Infants.—Whitridge reports the results of studies that were carried out with the purpose of determining whether or not bismuth compounds administered intramuscularly to twelve nonsyphilitic pregnant

women would produce changes in the skeleton of the newborn similar to those observed in the long bones of infants of syphilitic mothers who had received preparations of bismuth intramuscularly during pregnancy. The twelve women received weekly injections of 1 cc. of bismuth salicylate in oil for not more than eight administrations. In other respects antepartum management was conducted as usual, and the pregnancies progressed uneventfully and without complicating factors. Seven women were delivered within one week, one within eight days and four within from twenty-four to thirty-six days after the last administration of the bismuth compound. Roentgenograms of their children were taken within the first week of life. The roentgenograms of nine infants showed definite changes near the ends of the long bones. These changes consisted of areas of increased transverse bands of density similar to those described by Caffey. In two instances no changes could be detected and in one any alterations from the normal were so slight as to be questionable. In the two cases in which the roentgenograms were considered normal, the mothers had received eight and seven injections of the metal, respectively, and delivery took place within one week of the last injection. In the one questionable instance the bismuth compound had been given eight times and delivery occurred three weeks after the last administration. Apparently some factor other than the mere quantity of metal administered is involved in producing these changes. Ten of the twelve infants were normal full-term children and were well when discharged from the hospital. One infant died on the second day of life following a difficult breech extraction and death was undoubtedly due to trauma. Post-mortem x-ray examination of the skeleton showed well defined bands of increased density. At necropsy intracranial and intra-abdominal hemorrhages were discovered. Chemical tests for bismuth were negative when portions of bone from this infant were examined. A severe anemia developed shortly after the birth of the last infant. With repeated blood transfusions the child improved rapidly and was discharged two weeks later in good condition. The study supports Caffey's assumption that the changes in the long bones of infants of treated syphilitic mothers were produced by bismuth and not by healed syphilitic osteochondritis.

Surgical Treatment of Duodenal Ulcers.—According to Lewisohn, partial gastrectomy with removal of the ulcer is the operation of choice for duodenal ulcer. Opposition to gastric resection persists because of technical difficulties inherent in the operative technic. He believes that, if gastric resection was technically as simple as a gastro-enterostomy or a pyloroplasty, every surgeon would employ it. Exaggerated statements have been made about the inherent mortality and the magnitude of the operative procedure in gastric resection. With some experience and with proper organization, the mortality in primary cases

of gastroduodenal ulcers should not be higher than about 5 per cent. The mortality following a subtotal gastrectomy for gastric ulcers is usually higher than that following partial gastrectomy for duodenal ulcers. Yet gastric resection for gastric ulcers is considered by most surgeons as a justifiable procedure, whereas gastric resection for duodenal ulcers is considered too radical. It appears that opposition to the procedure is due to some extent to the abuse of the term "subtotal gastrectomy." The term implies that only a small stump of stomach is left. This term is fitting for the operation for high gastric ulcers. When one is dealing with duodenal or prepyloric ulcers the removed part represents a little more than one half of the stomach. Partial, rather than subtotal, gastrectomy is the correct term for this operation. The term "gastric resection" is also incorrectly applied to certain operative procedures. The surgeon should distinguish between a prepyloric or a postpyloric Finsterer operation. The Finsterer operation puts the ulcer at complete rest and reduces the preoperative hyperacidity considerably. Thus the method has a sound principle. The same cannot be said of the palliative resection of Madlener. If temporary cures follow this method, they probably occur independently of the operation, not because of it. Perforation and hemorrhage, the serious complications of duodenal ulcer, have been more frequent in recent years because duodenal ulcer is still considered a medical disease, even after repeated medical failures. The fact that a fair percentage of ulcer cases are refractory to medical treatment must be recognized. The economic factor may at times place the ulcer patient in the surgical group. While partial gastrectomy is far superior to gastro-enterostomy or pyloroplastic operations, it is not a definite safeguard against a recurrence. The ideal method for permanent cure of chronic duodenal ulcer still has to be found and it is possible that it will be along medical lines. At present when a series of medical treatments have failed, partial gastrectomy is the best method. It relieves the patient of many years of suffering, safeguards him against the serious complications of perforation or hemorrhage and effects a permanent cure in about 90 per cent of cases.

Malaria Simulating Acute Surgical Diseases of Abdomen.—Daniel discusses the confusing picture produced by abdominal pain, which may be a manifestation of malaria. Surgeons are familiar with the postoperative fever caused by the lighting up of a chronic malarial infection. These cases sometimes occur in temperate regions. Daniel reports nine cases of malaria simulating acute abdominal disease. Eight of the patients were encountered in a total of 266 patients with malaria admitted to the Vanderbilt University Hospital during the last thirteen years. An analysis of the cases reveals that the diagnosis of malaria was suspected and established in six cases because of the presence of leukopenia on admission. A rise in temperature was accompanied by a leukopenia, sometime after admission, in three cases. Two patients had an unexplained chill and the parasites were found in the routine blood smear. Sudden onset of severe abdominal pain occurred in six cases, and in three the pain was at first relatively mild and gradually increased in severity. Nausea was present in all cases and vomiting in eight. Only three patients had prodromal symptoms, headache and general malaise, and only three gave a history of previous attacks of similar abdominal pain. The past history of two patients was of significance in suggesting malaria as a cause of the symptoms. Chills occurred during the present illness in only three cases. The spleen of only one patient was felt, and he presented such marked abdominal tenderness and muscle spasm that neither the liver nor the spleen could be palpated until several hours after the parasites had been found and quinine was administered. The liver of only one patient could be felt. Three of the patients had a definite involuntary rigidity of the abdominal wall at the time of admission. The two patients who gave past histories of malaria had received inadequate treatment. The other patients had never had symptoms of malaria and had not received antimalarial treatment. The importance of painstaking, unhurried examination of the blood in similar cases is emphasized. Parasites are often found by the thick drop method when they are not numerous enough to be seen in smears. Repeated examinations of the blood were performed in five cases before parasites were seen. *Plasmodium vivax* was found in the blood of seven and *Plasmodium falciparum* in the blood of two patients. The usual criteria for differentiation of malaria from the common, acute surgical diseases of the abdomen were strikingly inadequate in most of the nine cases. Leukopenia was present in eight. It may be of considerable aid in suggesting the presence of malaria. The examination of a blood smear and of thick drop led to the correct diagnosis in five. The finding of malarial parasites in the blood of patients who present characteristic signs of intra-peritoneal disease does not exclude the possibility that such a disease may also be present.

Tumors of Lateral Aberrant Thyroid and Malignant Tumors of Thyroid.—According to Ward, the dividing line between benign and malignant tumors is nowhere less sharply drawn than in tumors of thyroid tissue showing papillary design. Fifteen cases of tumors of aberrant thyroid tissue found in the pathologic material of 4,274 operations are presented in detail. There were ninety-five malignant tumors in normally situated thyroids. Twelve of the growths of the aberrant thyroid were tentatively considered by the author as malignant and three as benign. Of three patients dead of lateral tumors, two had growths of the papillary type and one a malignant adenoma. Of the twelve malignant tumors, seven were either predominantly papillary or showed some characteristics of that growth, while five showed no tendency toward papilliferous change. The most common location of lateral aberrant tumors is along the course of the sternocleidomastoid muscles. The tumors were single in only three instances. The remaining twelve cases were instances of multiple tumors, forty-two located in the left side of the neck and twenty-nine in the right. In three cases there was no associated involvement of the thyroid. In papillary tumors a papillary tumor was considered malignant in the presence of microscopic evidence of invasion of the capsule, blood vessels or lymph nodes. Regional or distant metastases were considered gross evidence of malignant change. Multiple lateral tumors, whether accompanied by similar tumors in the thyroid or not, do not constitute evidence of malignant change by themselves, and the presence of lymphoid elements in lateral tumors does not necessarily indicate that they are metastases to lymph nodes. Many of the changes which would bespeak a malignant condition in other organs are seen in the thyroid as a response to stimulation of the gland to greater activity. There is little evidence that the change from a benign to a malignant tumor of papillary structure is not a reversible process. There is considerable difference of opinion as to the origin of lateral aberrant thyroid nodules. If lateral aberrant thyroid tissue develops from embryonal rests, as was suggested by Wegelin, its response to stimulation may be the formation of papillary growths. If the factors causing stimulation are removed or altered, the tumors may regress unless they have reached an irreversible stage or the individual biologic factor resistant to cancer in the host is lacking. The loss of this assumed factor may explain the progression to a malignant

growth in older persons, and the retention of it may account for the apparently benign course of many of these tumors in children. Dunhill has reported complete disappearance of recurrent lateral tumors in two children on administration of large doses of thyroid substance. However, in adults the danger that an irreversible change will take place or has already taken place is too great to warrant less than complete removal of all lateral tumors and, contrary to the opinion of Crile, the application of radiation as a postoperative measure. It may be worth while to administer thyroid substance to all adult patients with such tumors, especially to those showing a thyroid deficiency. The author points out that the statistical comparison of malignant tumors of lateral aberrant thyroid tissue with those arising in the thyroid proper shows that the former are found in a younger age group, that they are more equally distributed between the sexes and that the mortality rate is less than half as great. Despite the more favorable mortality rate, the ratio of recurrence is high. Only four of the fifteen patients have remained free from the disease after a single operative removal. There were two deaths from papillary tumors, one from pulmonary metastases and one the author believes was caused by metastases from a lateral nonpapillary tumor. In view of this he feels that a guarded prognosis should be given in similar cases and that more deaths will be found in the cases reported by other investigators if a sufficiently long period of observation is maintained.

Plasmacytoma of Thyroid.—Shaw and Smith report what they believe to be the first case of plasmacytoma arising in the thyroid. The tumor appears to be related to Riedel's chronic thyroiditis. The case is that of a childless married woman aged 50 presenting a swelling in the region of the thyroid. The swelling slowly increased in size. The patient's only complaint was a sensation of choking when she lay in bed with her neck extended. The swelling conformed in outline to the shape of the thyroid and was free from the overlying skin, which was slightly reddened and edematous, and from the sternocleidomastoid muscles. No abnormality but osteo-arthritis of the knees and shoulders since the age of 36 was found. The basal metabolic rate was within normal limits. A total thyroidectomy was performed. The neck presented a normal appearance eighteen months later. A maintenance dose of thyroid substance has been given daily. Clinical, macroscopic and microscopic study of the tumor revealed dominance of the plasma cell and the relative paucity of lymphadenoid tissue, and the macroscopic appearance and clinical history resembled that observed in cases of Riedel's chronic thyroiditis. Microscopically the growth was an almost perfect example of a plasma cell tumor. The one point of distinction between this case and cases of thyroiditis was the exceptional prominence of the plasma cell. There is a division of opinion as to whether these tumors are inflammatory or true neoplasms. The association in their case with the changes known as chronic thyroiditis suggests that lesions occurring diffusely in the neck and those arising as localized masses in the nasopharyngeal mucosa (and more rarely in other places) have a common cause. In all the reported cases of thyroiditis, syphilis and tuberculous infection were excluded, nor could pyogenic organisms be held responsible. There must obviously be other etiologic factors which initiate a stimulus resulting in destruction of the thyroid in an otherwise healthy person, or the growth of masses of tissue in the neck. The authors believe that their case affords a clue in the long-standing osteo-articular and periarticular trophic disturbances. The importance of the adrenal hormone in connection with the conductivity of the neural impulse in the sympathetic system suggests that there is an intricate and delicate mechanism by which the passage of physical stimuli between the central nervous system and the thyroid or other tissue is intimately associated with the endocrine secretions. They consider the changes occurring in their case as one aspect of the pathologic course of a condition which is itself uncommon, namely Riedel's chronic thyroiditis, and that these conditions are expressions of tissue cell hyperplasia following a physiochemical disturbance that may be dependent on a complex cycle of causes in part due to disturbance of the neural control and in part of endocrine origin. They conclude that the plasmacytoma in this case belongs to a type of plasma cell hyperplasia which may occur in conjunction with lymphocytic hyperplasia, the two cellular elements varying in different

cases. In some the plasma cell predominates, in others the lymphocyte, and in still others the two are present in more or less equal proportions. The ultimate course of such a hyperplasia appears to be governed either by local tissue reaction or by cessation of the initial stimuli. They conclude tentatively that these uncommon changes are due to an imbalance of the neuro-endocrine control of the tissue cells. Disturbance of the neural impulse or of the physiochemical mechanism results in abnormal stimuli productive of intensive proliferation of the connective tissue cells and hyperplasia and destruction of normal glandular elements. Plasmacytoma of the thyroid, chronic thyroiditis and other extramedullary plasmacytomas are all expressions of a common pathologic process.

Hyperplasias of Mammary Glands.—The study is concerned with contrasting the morphologic structure of supposedly precancerous lesions in the mouse and in man and with the endocrine disturbances underlying each. The phases of the problem investigated by Taylor and Waltman were (1) microscopic characteristics of the two major lesions of chronic mastitis (adenofibrosis and hyperplasia of the ducts), (2) clinical evidence of ovarian dysfunction in women with chronic mastitis, (3) gross and microscopic structure of the mammary glands of two strains of mice differing in their susceptibility to mammary cancer, (4) a search for evidence of a specific physiologic endocrine difference between the two strains and (5) a study of the mammary glands of mice after injection of various endocrine substances. The pathologic material consisted of mammary tissue removed at operation from 103 patients with chronic cystic mastitis. Clinical aspects of the disease of the breast and data on the reproductive and menstrual histories were available. The lesions were subdivided into four groups: distortion of the mammary architecture owing to hyperplasia of fibrous tissue or of normally formed acini (adenofibrosis), proliferation of atypical acini (adenosis) and inflammatory or neoplastic disease of the ducts. The acinar proliferation is the form of human mammary lesion most closely resembling abnormal proliferation developing in the glands of mice susceptible to mammary carcinoma. There are at least two separate entities which have been called chronic cystic mastitis. The first is characterized by a diffuse nodularity and by premenstrual pain. The basic microscopic lesion is fibrosis or adenofibrosis involving the interstitial fat and the periacinar tissue. The ducts are but slightly affected. The condition is analogous to adenomyosis of the uterus and should be termed adenofibrosis. The second type is characterized by a discharge from the nipple, often associated with palpable dilatation of the ducts near the areola. The microscopic alterations are edema of the lobules, dilatation of the ducts, periductal inflammation and possibly some hyperplasia of the lining of the ducts. The disease should be termed nonpuerperal lactation, periductal inflammation or duct hyperplasia. A third type is perhaps to be recognized in more or less local lesions, such as a single papilloma in the larger ducts or the isolated nodules of Schimmelbusch's disease. The clinical evidence of ovarian disorder obtained from the microscopic study showed that of forty-seven patients with painful nodular breasts only seventeen had borne children, while of forty-six patients with discharge from the nipple forty-one had children. All the patients with a simple milky discharge had been pregnant. This supports the claim that two distinct entities are being dealt with. Disturbances of the menses affect a minority of patients with chronic mastitis but are more frequent than in normal women. A decrease in the amount and duration of the menstrual flow in cases of painful nodular breast (adenofibrosis) was again evident in about a fifth of the cases. The consistency with which this rather uncommon anomaly of menstruation has been reported in this type appears to establish its association with the disease. Delay in menstruation may be present. Papillomas of the ducts and circumscribed adenomatous proliferations are to be regarded as nearly independent neoplasms, while the more diffuse processes, occurring before the menopause, are to a greater extent dependent on ovarian function. The significance of endocrine abnormalities in chronic mastitis assumes importance from the observation of mice susceptible to mammary carcinoma. Striking differences were observed in the spontaneous lesions resembling chronic mastitis in two strains of mice as early as the third month of life. The essen-

tial difference was a vast increase in the number of acini in the cancer susceptible strain. The mammary glands of these two strains are similar at birth. The hereditary factor is probably not in the gland but in stimuli which make themselves evident in morphologic change in the mammary gland early in the life of the animal. The early changes which eventually lead to spontaneous carcinoma in mice affect essentially the peripheral portions of the mammary gland. The more common characteristics of so-called chronic cystic mastitis were not observed to occur spontaneously in mice. The strain with excessive mammary proliferation had a much larger ovary with many more corpora lutea than the cancer resistant strain. Less striking differences were present in the adrenal and the thyroid. No differences in the anterior lobe of the pituitary were observed. However, the strains studied are not necessarily representative of all cancer susceptible or cancer resistant groups. The differences in the ovaries of the two strains indicate the need of morphologic examination of the ovaries of women with hyperplastic and neoplastic disease of the breast. The authors studied the effects of an excess of four different endocrine principles on the two strains. The basic difference, diffuse adenomatous proliferation of acini, was persistent no matter what endocrine principle was injected. Morphologically similar structures are sometimes seen in human mammary disease, but their presence does not constitute an essential feature of "chronic mastitis." The diffuse fibrosis or adenofibrosis, the most common form of benign mammary disease in women, has no morphologic counterpart in the mammary lesions of mice, whether spontaneous or induced by endocrine substances. Retained secretion in dilated ducts, moderate hyperplasia of the lining of the ducts and signs of periductal inflammation are closely imitated by lesions in mice which develop after prolonged administration of endocrine substances, especially estradiol. Complex neoplastic lesions occurring in the human breast, such as papillomas or proliferation of the epithelium, do not develop in the breast of the mouse either spontaneously or after prolonged administration of estrogens.

Hypertension and Unilateral Nephropathy.—Nesbit and Ratliff report nine cases of hypertension associated with chronic inflammatory nephropathy, three cases of chronic inflammatory nephropathy without hypertension, two cases of hypertension associated with obstructive nephropathy and one case of hypertension associated with sclerotic and cystic nephropathy (ischemic) resulting from trauma. Experimental and clinical

investigations have established a relationship between non-nephritic renal lesions and hypertension. Numerous cases of hypertension have been reported associated with unilateral and bilateral chronic sclerosing pyelonephritis. Vascular changes within the infected kidney associated with hypertension have been reported by most observers. That the same vascular changes may occur in chronically infected kidneys without associated hypertension seems evident from cases presented. Nephrectomy appears to be a justifiable procedure in cases of unilateral pyelonephritis with associated hypertension. Improvement may be expected in this group provided the functioning capacity of the remaining kidney is unimpaired. Secondary vascular changes elsewhere in the body may militate against recovery. The authors point out that the results of treatment in their two cases of obstructive nephropathy with hypertension clearly demonstrate that the causal relationship between obstruction and hypertension is not due to renal insufficiency. They suggest a reflex rather than a toxic or humoral factor, since nephrostomy was as effective as nephrectomy in returning the blood pressures to a normal level. The one case of malignant hypertension occurred ten years after traumatic injury to the kidney. The possibility of a causal relationship between ischemic changes in this kidney and the hypertension suggests the advisability of periodic blood pressure determinations in all cases following traumatic injury of the kidney. The development of hypertension in such circumstances would appear to make prompt nephrectomy a rational procedure.

Urologic Manifestations of Appendicitis.—Ehler reviews subjective and objective manifestations of appendicitis that might be confused with those of the urogenital tract, in particular the lower urinary tract. The opposite situation is not infrequent. He classifies urologic manifestations of appendicitis as follows: (1) disorders of micturition (frequency of urination, pain on urination, dysuria and retention of urine), (2) abnormalities of the urine (hematuria, pyuria, albuminuria and anuria), (3) pain in the right testis or retraction of the testis, (4) renal or ureteral colic and (5) tenderness in the right costovertebral angle. If disorders of urination were due to sympathetic irritation, as Deaver suggests, one would expect to find them associated with negative urinary changes, but such is rarely the case. In the presence of symptoms there are usually found varying amounts of blood, pus or casts, along with micro-organisms, in the urinary sediment. Such observations are much more compatible with the theory of intimate contact of the appendix or the inflamed peritoneum with some part of the urinary tract. Operative and postmortem observations demonstrated that this is the usual occurrence. The site most frequently involved is the right ureteral wall at the brim of the bony pelvis. In place of "toxic hematuria," "reflex renal congestion" and similar concepts, one may find a more logical and more easily verified solution in the frequently found intimate association of the inflamed appendix with the right ureteral wall. Pyuria, both slight and massive, not infrequently encountered in appendicitis, may be similarly explained. An inflamed appendix in actual contact with the right ureteral wall produces a periureteritis and ureteritis that result in pus cells passing into the ureteral lumen and eventually appearing in the urine. An actual pyelitis depending on a lymphogenic ascent of colon bacilli up the periureteral lymphatics to the kidney may, and in all probability does, play some part. In an analysis of 300 cases of pyelitis, Van Duzen listed appendicitis as being the probable etiologic factor in 7.6 per cent. Massive pyuria may be seen following the rupture of an appendiceal abscess into the bladder. Albuminuria seen in appendicitis may usually be accounted for by the pus and blood cells present in the urine at the same time. Anuria is a rare accompaniment. According to Cope, testicular pain occurs in about 5 per cent of the cases of appendicitis. It may precede the abdominal pain by an hour or two. Pain resembling renal or ureteral colic is frequently seen when the appendix or its inflammatory exudate is in contact with the renal pelvis or the right ureter. Tenderness in the right costovertebral angle is seen in many cases of appendicitis, particularly in those in which the appendix occupies a retrocecal position.

Gastroscopic Examination.—The concept of gastric disease has undergone considerable change since the introduction of the Wolf-Schindler flexible gastroscope. It is now possible to see the inside of the stomach and to observe changes in the gastric mucosa not demonstrable by any other method. Benedict discusses the use of the gastroscope in the various gastric disorders and cites illustrative case histories. On the basis of observations extending over a period of six years, he concludes that gastroscopy is a safe procedure, easily performed and well tolerated by most patients, and that the information obtained is of great value to the surgeon. Since gastritis is the commonest disease of the stomach and since massive hemorrhage may come from gastritis alone, all patients with unexplained gastrointestinal bleeding should have a gastroscopic examination. Gastritis which frequently accompanies gastric or duodenal ulcer must be recognized and localized, particularly if surgical intervention is being considered. Since postoperative gastritis is a definite entity best recognized by gastroscopy, gastroscopic examination should always precede secondary intervention. In both gastric and duodenal ulcers the associated gastritis, which may seriously modify the medical or surgical management of the patient, is best studied by gastroscopy. Gastric ulcers not previously suspected have been demonstrated by the method. The gross appearance of the lesion, whether clean and sharply defined, as in benign ulcer, or dirty and irregular, as in malignant ulcer, and its response to treatment are points of great importance that should be studied by gastroscopy. The method is of value in the diagnosis of carcinoma in determining its location and extent and in differentiating benign and malignant lesions.

Sulfanilamide for Scarlet Fever.—According to Silverman, there has been a striking change in the character of scarlet fever over the last seventy-five years, the mortality in 1938 being but one one-hundredth of that in 1861, which was 100 per hundred thousand. This increasing mildness caused some difficulty in evaluating the therapeutic effects of serum and of sulfanilamide. The latter exerts no evident influence on the toxic phase of scarlet fever. The author refers to several studies which suggest that sulfanilamide may lessen the incidence of suppurative ear complications. No series large enough to be accepted as conclusive were published. As a

basis for statistical consideration he analyzes a nonepidemic series of eighty-four cases admitted to the Syracuse City Hospital last year; forty-three patients were given sulfanilamide and forty-one served as controls and were given serum. A smaller ratio of suppurative otitis media was encountered in the sulfanilamide group. Of twenty-three toxic patients on admission given sulfanilamide suppurative ear conditions developed in two as compared to seven of nineteen similar control cases. Nevertheless definite conclusions are unwarranted on the basis of a small series. Sulfanilamide does not replace antistreptococcus serum in cases of toxemia. In severe cases with toxic and septic phases, combined treatment is indicated. For the sick patient it is justifiable, under proper safeguards, to incur the risk of serum reaction or drug intolerance.

Miniature Chest Films.—Potter and his co-workers find that a 4 by 5 inch film reproduction of a fluoroscopic image is small enough to constitute real economy and yet large enough to be readily interpreted without enlargement. The technic of producing this film comprises a modern x-ray installation with rotating anode tube capable of handling 400 milliamperes of current at from 60 to 80 kilovolts, an impulse timer and a tube-screen distance of 50 inches (125 cm.). The time necessary for exposure depends on the thickness of the chest and varies from one twentieth to four twentieths of a second. The fluorescent screen used is nearly seven times as fast as the usual Patterson screen. The lens has a rating of 1.5. This lens is capable of producing a sharp image in an area $3\frac{3}{4}$ inches in diameter on the 4 by 5 inch film. For the best results the patient's chest image must be centered within this area. To test the capacity of this film 1,610 patients were examined with both the regular 14 by 17 inch film and the miniature film, taken at the same time. The readings were interpreted and recorded independently. A total of 271 patients were found to have various types of active tuberculosis. Five of the minimal lesions were missed in the interpretation of the miniature films. Two other minimal lesions were called "healed primary." All these lesions were small and might easily have been missed in a regular film taken at a different angle, a slightly different depth of breathing or with less perfect technic. In nearly every instance these missed lesions were superimposed over rib shadows. This constituted an error of 2.6 per cent. There were five small lesions of active primary infection or enlargement of the lymph nodes. None of these were missed in the miniature film. Of fifty-four dry pleurisies nine were missed, an error of 17 per cent. This unnecessarily large error was due to too much attention being given the apexes with the consequent throwing out of focus of the bases. This has since been balanced so that the bases are nearly as well demonstrated as the apexes, with the result that this error can be decreased with a little extra care. From the regular films twenty-eight cases were classified as "minimal healed tuberculosis." Eight of these were not considered sufficiently significant in the miniature film to be mentioned. If a descriptive report had been given, it is likely that no significant error would have resulted. Two of twelve cases of valvular cardiac lesions from which symptoms resulted similar to those found in tuberculosis were called mixed but, when the errors were reviewed, they were found to be oversights as the signs were definitely there. Some nontuberculous lesions, especially those at the base, were missed at first because too much concentration was given to the apical areas. Basal detail can

be obtained and interpreted when one has learned to distinguish between shadow differences in the miniature and in the regular films. The authors now apply the method to new patients coming to the tuberculosis clinic without taking a large film except when there is a questionable appearance in the small film. This has proved satisfactory in the two months during which 1,719 persons have been examined. The authors believe that the method can be carried out economically enough to make it practical in surveying large numbers without a preliminary tuberculin test, even in groups in which the reactor rate is low. There is need for only one visit by the patient. Only a few patients need to be reexamined, whereas with the preliminary tuberculin test at least two visits are required. There is always a loss growing out of the fact that many reactors fail to appear for x-ray examination. This amounted to 4,719 out of 31,803 reactors, or 14.8 per cent, in a recent study in Detroit. Most persons would rather have a roentgenogram taken than submit to a tuberculin test. There is also the possibility of detection of nontuberculous lesions of the heart and lungs. The cost of taking the 4 by 5 inch film is reasonable. These small films are easily handled, can be interpreted at the same speed as the large films, and require little space for storage. The method has definite advantages over full size celluloid films, sensitized paper films, full size films and 35 mm. films in accuracy, in cost or in both.

Prognosis of Pulmonary Tuberculosis.—Gershon-Cohen and Farrell investigated the prognostic possibilities of roentgenologic examination of tuberculous patients. They set up a standardization in diagnosis which included the extent and distribution of lesions, type of lesions and cavities. The changes on one side bear on those of the other side in a given relationship. The lesions were divided into four benign and four malignant groups. They have analyzed more than 600 cases and their preliminary estimate reveals that their prognoses were correct for approximately 80 per cent. In order to limit the analysis to the x-ray examination, the clinical picture and laboratory observations were excluded from all prognostic considerations. They believe that, when the same cases are reviewed to include these additional data, a better average of accuracy will be achieved. Their best prognoses were made in the more advanced benign and virulent groups. In the sanatoriums in which the analysis was made, most of the cases were benign or virulent to a moderate or advanced degree and the same held true in the dispensary practice. This would seem to reemphasize that, by the time the x-ray examination is asked for, pulmonary tuberculosis has passed beyond the early stages, in which event no one, the roentgenologist included, can foretell from a single examination the progress of the disease. Serial examinations can be resorted to and a fairly accurate prognosis arrived at in a few weeks.

Nutritional Anemia in Debilitated Children.—Somerford reports on 201 children attending the outpatient department of the Royal Manchester Children's Hospital during 1938. The children were undernourished and appeared anemic but had no organic disease. Red cell counts of 4 million or less per cubic millimeter and 70 per cent or less of hemoglobin were considered as anemic. The ages of the children varied between 10 weeks and 13 years and 9 months. One hundred and seventeen, or 58.3 per cent, were found to be anemic with red cell counts between 3 and 4 million. Anemia was more prevalent in the male sex. About 45 per cent of the mothers were anemic. The red cells were chiefly normocytes with a mild degree of anisocytosis and poikilocytosis. Nucleated red cells were seen occasionally. The number of platelets was normal or increased. The leukocytes were within normal limits. Sixteen children and one mother had an anemia of the microcytic type such as may be associated with iron deficiency. The greater number of ill nourished children were among the wealthier families, but the proportion of anemic to nonanemic children was roughly the same in the three financial classes. Most of the children were breast fed. Exercise seemed to be fairly adequate in most cases, but it is doubtful whether hours of sleep were sufficient, particularly among the poorest. The size of the family had little effect on whether anemia was present or not. Vitamin C deficiency was found in twenty-one of sixty-three patients examined. Forty-one of the wealthier ones were deficient, twenty-two of the poorer class. Three factors appear to play a part in the production of malnutrition and nutritional anemia: 1. Poverty. 2. A slackening in home discipline, which permits the child to stay up late, and not to eat food he does not like; this factor accounts for the much larger percentage of vitamin-deficient children among the wealthier families. 3. Some psychologic influence; this is seen in anxious and hypersensitive children the offspring of nervous, highly strung mothers. The purely nutritional cases would be better off if dealt with away from the hospital atmosphere. After a preliminary examination to exclude the presence of disease, they should be returned to their welfare workers, women intimate with the home conditions and respected by the mothers.

Lederer's Anemia.—The literature on Lederer's anemia, according to Atkinson, comprises thirty cases in children and twenty-nine in adults. In most cases the disease begins acutely with exhaustion, profound asthenia, gastrointestinal symptoms, swelling of the abdomen, severe headache, pains in the limbs, tonsillitis and pharyngitis. An icteric tinge of the sclera and skin may be present. There is, as a rule, intermittent fever of urobilin and may contain casts. Retinal hemorrhages are atrophy of the disks have been described. Hemoglobinuria is often present. Hemoglobinuria was present in eleven of the thirty cases in children. The blood picture is characteristic. There is an acute hemolysis evidenced by hemoglobinuria, by hyperbilirubinemia, by increased excretion of urobilin in the urine and feces, by fragility of the erythrocytes and by the abnormally increased blood regeneration as revealed by the numbers of reticulocytes and erythroblasts. The color index is often above 1. The hemoglobin is reduced in amount, the smallest recorded as low as 10 per cent. The red cell count is much below normal. Leukocytosis is nearly always present. The cause of hemolysis is a toxic factor the exact nature of which is unknown. Lederer's anemia is more frequent in the male, twenty-one and nine, respectively. The diagnosis is based on the acute onset, rapid anemia with no apparent cause, the evidence of hemolysis and the rapid cure resulting from transfusion. The outlook is grave if untreated but favorable if the proper treatment is instituted. Blood transfusion is the treatment of choice. Iron is of some value.

Subcutaneous Implantation of Hormone Tablets.—Loeser implanted female hormone tablets in two women and male hormone tablets in ten. The two women in whom estradiol tablets were implanted had theretofore been sterile. Both had infantile uteri, desired children and had been treated unsuccessfully with female hormones and anterior pituitary lobe preparations. The result of the implantation was negative in the first patient, as the tablets were expelled ten days after their insertion, being implanted too near the skin. The large quantity of estradiol in the second patient depressed the function of the anterior lobe of the pituitary. As a result, maturation of the ovum and menstruation did not occur. Local action of estradiol on the uterine muscle and mucous membrane of the uterus became visible. The uterus grew and the mucous membrane became converted into cystically proliferated endometrium and was cast off gradually by hemorrhage. After the hormone tablets were removed the anterior lobe gradually recovered, the hibernating ovary was stimulated by fresh gonadotropic hormone produced in the anterior lobe, ripening of the ovum occurred again and hence there was normal menstruation. The muscular apparatus of the uterus had been substantially strengthened and was now able to draw up the semen, which it had previously been unable to do because of muscular deficiency. The patient became pregnant. Of the ten women given male hormone implants five had uterine fibroids, one functional bleeding, two chronically recurring mastitis and multiple nodules in the breast and two mammary cancer. The implantations controlled in some measure menorrhagia caused by fibroids in all the patients, and successfully in three. Male hormone did not influence existing recurrences of carcinoma of the breast following an operation or roentgen treatment. To what extent male hormone can have a prophylactic action against such recurrence is not yet determined. Improvement was obtained in the two women with chronic mastitis. All the patients acknowledged a feeling of well being, more balanced moods and clearer thinking, and some professed a greater determination.

Epidemiology of Poliomyelitis.—Burnet reports the experimental work on the Victorian poliomyelitis epidemic of 1937-1938. The infection did not produce poliomyelitis antibody; certain children with initial antibody nevertheless suffered from paralytic infection. Cynomolgus monkeys could be infected with the local virus by ingestion or by pharyngeal swabbing. A study of the age incidence of poliomyelitis led to the conclusion that a change in the character of the disease has taken place in the last thirty or forty years. In the earlier period poliomyelitis was essentially an adult infection with incidental disorder of infants, while the present epidemic of poliomyelitis is a disease of childhood, spread by child contact. Poliomyelitis virus strains derive eventually from a virus which, prior to the end of the nineteenth century, was responsible for frequent infections of some part of the nasopharyngeal mucosa. Occasionally primary infection by the virus in unimmunized persons resulted in spread of the virus to the central nervous system and clinical paralysis. This happened only on first infections which, owing to the wide diffusion of the virus, could naturally occur only in very young children giving rise to the name "infantile paralysis." At this period the virus was capable, as influenza virus is today, of producing superficial infections in adults or older children with a basic immunity from former infection. This immunity was sufficient to prevent the spread of the virus to the central nervous system. With the advance of modern sanitation, opportunity for the free diffusion of the virus became more limited and a larger proportion of children passed through infancy without being infected. This provided a new means of spread for the virus by contact of susceptible children instead of transfer between partially immune adults. In this new biologic environment the virus gradually changed its character, becoming more infectious for children, less capable of infecting adults and more highly neurotropic. When the neurotropism is high, recent strains appear to be capable of overcoming an immunity which would have provided a solid protection against paralytic infection by strains of the earlier type. The present situation in a community such as Victoria is that there is probably still a good deal of the old type poliomyelitis virus infection, but that this is diminishing and is not often transferred to infants. The dominant strains are now spread like measles, essentially by child contact. A single infection does not provoke the appearance of antibody, and immunity to reinfection is probably only temporary. Previous infection with an antibody-producing strain does not insure immunity from paralysis by an epidemic strain. Infection occurs by inhalation or ingestion of contaminated saliva from an infected child. The primary focus is probably produced in the pharyngeal mucosa, and infection may reach the central nervous system by a variety of nerve paths. The olfactory route is probably an unusual one. Resistance to paralysis by epidemic strains develops with age, irrespective of specific immunologic factors. The Australian experience is that resistance to paralysis is greater in the warmer regions and that even a highly virulent strain may produce a small proportion of paralysis. For as yet unexplained reasons an epidemic may cease before all the susceptible population has been involved. On this basis the outlook for controlling the disease is not promising. Control by individual protection, vaccination, passive protection with human serum, chemical blocking of the olfactory area and protection by public health measures are all wanting. A close

investigation of the influence of climate and other environmental factors on the course of epidemics might suggest practical measures of individual protection. As epidemics nearly always terminate with the onset of cold weather, a "slowing down" of the epidemic by isolation and restriction of the aggregation of children may result in a large number of the susceptible being still untouched when climatic or other nonspecific factors terminate the epidemic. In six Melbourne districts during the 1937-1938 epidemic it was evident that every effort for the isolation of young children should be made to prevent infection.

Medulloculture in Diagnosis of Typhoid and Paratyphoid.—Ling and his colleagues made a detailed study of medulloculture in thirty-eight patients suffering from typhoid and paratyphoid. Of 110 medullocultures and an equal number of hemocultures performed on the thirty-eight patients, both showed positive growth in thirty-one instances and negative in thirty-three. Medulloculture yielded a positive growth in forty-four instances in which a hemoculture was negative. Only two medullocultures failed to demonstrate the organism in which hemoculture was positive. The average time required for growth in medullocultures was shorter than for blood cultures, indicating heavier infection with more organisms in the bone marrow than in the blood. Medulloculture makes earlier bacteriologic confirmation of the clinical diagnosis possible. In typhoid the main agent of defense is the reticulo-endothelial cell. Since the bulk of reticulo-endothelial tissue is situated in the bone marrow, spleen and liver, not only are the characteristic pathologic changes to be found there but the invading organisms as well. Most of the positive growths from the sternal marrow and blood occur during the febrile period. With medulloculture the organisms may still be isolated when the temperature has been normal for two weeks. This persistence of the bacillus in the bone marrow may explain the relapses of typhoid and paratyphoid. The bone marrow serves as a depot of *Bacillus typhosus* and *Bacillus paratyphosus* to the circulating blood. The presence of bacilli in the bone marrow is not responsible for the clinical symptoms although it undoubtedly signifies active infection. But when the bacilli are liberated into the blood stream and endotoxins are set free, the foreign proteins in the blood give rise to fever and other symptoms and signs of toxemia. Medulloculture has thus possibly opened a new field in clinical investigation of typhoid by enabling one to determine the possibility of relapse. An etiologic diagnosis may still be established in patients seen for the first time as late as two weeks after the acute stage is over.

Gynécologie, Paris

38:517-564 (Sept.-Oct.) 1939

- *Diethylstilbestrol, Synthetic Estrogenic Substance. J.-A. Huet, R.-J. Comte and A.-D. Herschberg.—p. 517.
Grave Familial Icterus of the Newborn: Case. H. Vertruyen, F. Lévy and L. Vandiest.—p. 553.

Diethylstilbestrol, Synthetic Estrogenic Substance.—Huet and his associates employed diethylstilbestrol in forty-six cases of gynecologic disorder. The substance was found to be effective in genital infantilism, in certain forms of oligomenorrhea and dysmenorrhea, in functional disorders of the menopause and in a number of hypophysis-ovarian disturbances. The treatment was successful in 77 per cent of the cases of menstrual dysfunction and in 82 per cent of menopausal disturbances. In the latter it counteracted the hot flushes, the profuse sweats and the vasomotor symptoms. The untoward secondary effects of this treatment were few. In 10 per cent of the cases the complications were benign. They consisted of attacks of weakness and nausea, which disappeared in the course of treatment. These complications were observed especially in women of the premenopausal and menopausal age. In about 3 per cent of the cases total gastric intolerance existed but its symptoms ceased when the medication was discontinued. The therapy with the synthetic estrogenic substance has advantages over that with the natural estrogens. Diethylstilbestrol is highly effective when administered by mouth, is easily handled and is relatively inexpensive. The fact that it is a powerful therapeutic agent necessitates an exact etiologic diagnosis and close clinical supervision in order to avoid disappointments. The authors recommend a dosage of 2 mg. of diethylstilbestrol daily given in two doses (morning and evening), far from meals, from the eighth to the eighteenth day, counting from the first day of the menstrual period. If an immediate menstrual flow is the object, the substance can be given for three days before the presumed onset of menstruation in a dose of 5 mg. daily. In the presence of hypophysis-ovarian disturbance 3 mg. daily for three days is recommended, beginning with the second day of menstruation. In cases of dysmenorrhea caused by uterine hypoplasia, 5 mg. is given on the day before the onset of the menstrual flow. In certain oligomenorrheas the dose is reduced to 1 mg. daily for ten days, in order to avoid too abundant hemorrhages.

Prolonged Pregnancy.—Fruhinsholtz and Richon discuss the etiology of prolonged pregnancies, with special reference to familial and individual involvements, on the basis of 128 (0.65 per cent) cases in 19,893 deliveries, thirteen (1 per cent) of the cases terminating fatally. Only those pregnancies were considered as prolonged that extended beyond the 300th day after the last verified menstruation, with a maximal terminal range of 351 days. Ninety-two deliveries (about 72 per cent) occurred between the 301st and 314th day, one on the 351st day. The authors regard prolonged pregnancies not merely as accidental variations of normal pregnancies but as possessing distinct pathologic implications, discoverable in the family and personal history of the patient. Among the pathologic factors observed in eighty-one (63 per cent) of the cases were found premature deaths and insanity (fourteen cases), multiple infant mortality (27.7 per cent) and coexisting physical abnormalities such as obesity, strabismus, exophthalmic goiter and epilepsy in sixteen cases. The body weight of the children at birth exceeded normal standards (in seventy cases it was between 3,000 and 6,000 Gm.) but no correlation was noted between greater body weight and deaths (the child weighing 6,000 Gm. died in utero). Placental weight likewise showed a higher curve. In fifty-five cases it was between 600 and 1,000 Gm. Infant mortality (10 per cent) in overdue pregnancies also surpassed the normal death rate, was equally divided between male and female infants but stood in no relation to the number of days of the child's intra-uterine existence. No deaths were due to obstetric interventions of a

mechanical nature. The personal history of the patients disclosed delayed initial menstruation (in thirty-nine cases between the fifteenth and twenty second year) and delayed conception (in twenty-three of thirty-four primiparas from six months to five years after marriage, once after thirteen years). These retardations are attributed by the authors to an endocrine insufficiency of a hypophysial character. The average duration of labor was also higher, from eighteen to twenty-one hours in primiparas, ten and one half hours in multiparas. Only six of the 128 patients reacted positively to the Wassermann test. Yet syphilis, though inconspicuous in the clinical picture, is believed by the authors to be ultimately and hereditarily chargeable with the various familial and individual pathologic conditions noted in these cases. Fetal malformations were relatively frequent. Tuberculosis and alcoholism were infrequently observed. Primiparity and multiparity were found etiologically to be of no significance. Intervention was resorted to only in exceptional cases and was limited to endocrine medication.

Reflections Preparatory to Experimental Research on Role of Sympathetic in Articular Pathology. S. de Sèze, G. Guiot and J. Serane.—p. 233.

*Oral Treatment of Trachoma with P-Aminophenylsulfamide. F. Jasseron and G. Morard.—p. 234.

*Sulfanilamide Derivatives in Treatment of Trachoma. L. Poleff.—p. 235.

*Improved Process of Method of Armand-Delille to Determine Presence of Koch Bacilli in Gastric Contents. L. Koganas and D. Nakanas.—p. 236.

Oral Treatment of Trachoma with P-Aminophenylsulfamide.—Jasseron and Morard call attention to oral treatment of trachoma with p-aminophenylsulfamide and point out that in their experience this substance showed the best results in the chemotherapeutic treatment of trachoma. The authors treated nearly 200 patients. Subjective symptoms, such as pain, photophobia and lacrimation, disappeared in forty-eight hours; pannus and infiltration of the cornea were resorbed in eight days; corneal ulcers acquired epithelium in thirty-six hours; cicatrization was accelerated and clinical recovery took place in three weeks in 75 per cent of the cases. Secondary infections with Weeks's bacillus, diplobacilli of Morax, pneumococci and gonococci were sterilized in four days. The authors recommend for adults ingestion of 20 Gm. in thirteen days, for children aged from 8 to 12 years 12 Gm. in twelve days, and for children aged from 4 to 8 years 7 Gm. in twelve days in decreasing dosage. Limited local treatment is advised.

Sulfanilamide Derivatives in Treatment of Trachoma.—According to Poleff, instillation of sulfanilamide derivatives into the eye caused conjunctival hyperemia with dilatation of the vessels, while subconjunctival injections were followed by intense hemorrhage at the place of injection. Repeated instillations and subconjunctival injections in five cases were not followed by sterilization of the bacterial flora of the conjunctival sac, while silver nitrate and ethoxydiamino-acridine lactate produced rapid diminution of the bacteria and general improvement. Intramuscular injections alternated with oral administration of sulfanilamide derivatives were followed by notable decrease of bacteria in the conjunctival sac; however, the final results were not satisfactory. Oral and intramuscular administration of sulfanilamide derivatives together with the usual treatment of trachoma produced very satisfactory results in fifteen malignant cases. Pallor and rapid loss of weight in the course of sulfanilamide therapy are symptoms of intolerance to the drug.

Improved Method of Determining Tubercle Bacilli in Gastric Contents.—Koganas and Nakanas point out that tuberculous patients do not always expectorate but may swallow their sputum or else scanty pulmonary secretion may get into the stomach without provoking a cough. A considerable number of patients have Koch bacilli in the stomach. Examination of the gastric contents by the improved Armand-Delille method renders quick diagnosis possible. The method consists of examining the stained centrifuged residue of the gastric contents. In the absence of typical bacilli the residue is thoroughly mixed with equal parts of 4 per cent sodium hydroxide and after centrifugation the residue is neutralized with hydrochloric acid. Part of this is dried and is examined for Koch bacilli while

the rest is cultured or injected into guinea pigs. The authors examined 115 tuberculous patients with this method and found Koch bacilli in the stomach of most patients who did not expectorate. In only 26 per cent of the examined cases were the authors obliged to culture and inoculate guinea pigs. The authors regard this method superior to laryngeal smear or stool examination.

*Contributions to Vaccine Therapy of Radicular Symptoms in Tabes. L. von Angyal and K. Gyárfás.—p. 65.

Psychopathology of Simple Schizophrenias. J. Wyrsh.—p. 75.

Aspects of Extrapyramidal Motor System. E. Grünthal and K. Hartmann.—p. 107.

Vaccine Therapy of Radicular Symptoms in Tabes.—Von Angyal and Gyárfás used Hilgermann's spirochetal vaccine in nineteen cases of locomotor ataxia. The vaccine was injected subcutaneously into the anterior part of the thigh at intervals of two weeks. The initial dose was from 0.5 to 1 cc. When the reaction was too severe, the dose was reduced to 0.1 or 0.2 cc. The total number of injections varied between one and twelve. Reflex disturbances such as hypotonia and dysuria did not respond to the treatment. Complaints ascribed to radicular irritation reacted well. Shooting pains, present in fifteen cases, ceased altogether in five and were improved in nine. Gastric crises (eleven cases) responded nearly as well; they stopped altogether in two cases and there was an improvement in seven. Vesical and intestinal crises (one case each) were controlled for the time being. The impression was gained that intense local or focal reaction constitutes a favorable sign.

*Treatment of Suppurative Mastitis and Acute Abscesses Without Incision. E. Pagliai.—p. 389.

Septicemia from Streptococcus Viridans of Dental Origin Without Endocarditis: Recovery of Patient. A. Fabris.—p. 403.

Treatment of Suppurative Mastitis Without Incision.—The treatment advised by Pagliai consists of repeated puncture of a breast abscess, aspiration of pus and injection into the cavity of an ointment made up of equal parts of pure cod liver oil and white petrolatum. He has obtained satisfactory results from this treatment in more than 100 cases. The first puncture is made with the aid of a 1 per cent procaine hydrochloride anesthesia of the superficial and deep tissues about the abscess. The following punctures are made through the route followed by the needle in the first puncture. The treatment is repeated every other day. It is discontinued altogether as soon as secretions assume a sanguineous appearance. Lactation is temporarily discontinued but is preserved. The breast is emptied every three hours with a breast pump and is dressed with warm wet compresses. If the nipple is fissured it is gently washed with boiled water after each withdrawal of milk and is dressed with cod liver oil ointment. As a rule, acute suppurative mastitis is controlled by this treatment in from one to two weeks, after which lactation is recommenced. Repeated puncture of the abscess, aspiration and injection of cod liver oil ointment gave prompt satisfactory results in acute abscesses and acute suppurative lymphadenitis.

Orbital Emphysema Caused by Fracture of Ethmoid Bone After Head Hit Surface of Water During Diving. A. Meyer zum Gottesberge.—p. 66.

Pigment Degeneration of Retina with Deaf-Mutism.—Weber discusses the question of the combined appearance of degeneration of the pigment of the retina with deaf-mutism being due to an internal causal connection or to hereditary anomalies

existing side by side. A family in which pigment degeneration and deaf-mutism concurred was studied. The genealogic tree of the family failed to furnish an answer to the question of how the combined two disorders were to be explained. It is noteworthy that the siblings who are affected suffer from the two disorders simultaneously. This combined appearance creates an impression that the two defects belong together, the more so since in the three cases in which the defects occurred the vestibular nerve did not respond to stimulation. However, the assumption of the common origin of the two hereditary disorders is contradicted by the fact that the pigment degeneration of the retina has been known to concur not only with the recessive deaf-mutism but also with the dominant hardness of hearing of the inner ear. The combination of deaf-mutism with pigment degeneration has raised the question of whether it is due to a hereditary combination elicited by a common gene. The opinions on this subject are contradictory. The author reviews the factors cited in favor of a unitaristic origin as well as those favoring a separate and independent hereditary transmission. Indicative of an independent hereditary transmission are the essential difference of deaf-mutism and pigment degeneration, the fact that in most instances the two disorders appear separately and that the combination is the exception, the promotion of the combination by blood relationship of the parents, the concurrence of feeble-mindedness with one or the other or with both of the defects and the occurrence of other combinations. Nevertheless the author feels that the acceptance of an independent and separate hereditary transmission must be made with reservations, because the examined material is insufficient to permit a complete survey of the problem. The final answer will probably be similar to that given by Siemens, namely that the apparent correlation of recessive hereditary defects in the children of parents related by blood is due to identical descent, because, since all recessive defects are more frequent with inbreeding, it is self evident that they frequently concur among siblings or even in the same person.

 *Experiences and Results with Chemotherapeutic Modification of Venereal Lymphogranuloma and Other Virus Diseases. F. Bär.—p. 344.

Chemotherapy of Venereal Lymphogranuloma and Other Virus Diseases.—Bär resorted to intracerebral inoculation of mice with emulsions of the brain substance of mice that had a severe form of venereal lymphogranuloma. The comparative study of various derivatives of the sulfanilamide group was done by repeated subcutaneous injections of the preparation to be tested. The first dose was usually administered one hour after the infection with the virus of venereal lymphogranuloma. The results of the investigations are recorded in graphs, which reveal that a number of sulfanilamide preparations exert a chemotherapeutic influence on experimental venereal lymphogranuloma. Among the large number of preparations tested, the most effective were dimethyldisulfanilamide, monomethyldisulfanilamide, and disulfanilamide, azosulfanilamide, a soluble form of the latter, benzylsulfanilamide, sulfapyridine, the azo body 33 of Girard and others. The repeated administration of these compounds either prolonged the life of the animals or produced complete survival, in contradistinction to the untreated animals, which generally died. After pointing out that the sulfanilamide preparations have been found effective also in human infections with venereal lymphogranuloma, the author suggests that the therapeutic action is probably due to the fact that the injected preparation inhibits the development of the virus and that after this impairment the defensive powers of the organism complete the destruction. The author was able to corroborate the observation that in some of the animals the virus remains viable for a time after the administration of the

preparation and that some of the animals which were cured developed an active immunity against a renewed inoculation with the virus of venereal lymphogranuloma. The critical evaluation of results obtained thus far by various investigators in the chemotherapy of virus diseases show that only in venereal lymphogranuloma, in trachoma and in certain symptoms produced by the Rickettsia group of organisms can a noticeable therapeutic effect be observed; all other experimental results still lack verification.

 Endophlebitis Hepatica Obliterans. P. Formijne.—p. 932.
 Synthetic Estrogenic Substances in Gynecology. W. M. J. Schellekens.—p. 940.

Resistance to Sulfapyridine in Pneumococci.—Mulder and his associates demonstrated in experiments on mice that a strain of pneumococci (type I in America) which is highly sensitive to sulfapyridine may rapidly develop a resistance against that substance. At first the resistant strain is less virulent than the sensitive strain, but after a few mouse passages it regains its maximal virulence. Resistance may be complete in the presence of full virulence. In the early stages of resistance the strain may cause a prolonged bacteremia in spite of treatment with sulfapyridine; later this phenomenon disappears. The possibility of the development of a resistance to chemotherapy must be considered in the clinic. Severe pneumococcal infections should be treated from the onset with large doses of sulfapyridine, and type specific antiserum could perhaps be combined with it.

Saline Enema in Postoperative Intestinal Paralysis.—The large number of remedies recommended to stimulate peristalsis in postoperative ileus indicates, according to Suren, the inadequacy of these measures. A comparatively simple and yet highly effective procedure employed by Stahnke in Ludwigshafen, also described by Genkin and Miljawskaia (*Arch. f. klin. Chir.* 176:156 [Aug. 24] 1933; abstr. THE JOURNAL, Nov. 4, 1933, p. 1521) was employed by the author in several hundred cases. Two tablespoons of sodium chloride is dissolved in 150 cc. of lukewarm water and introduced as a drop enema high into the rectum. The enema may be effective before it has been completed, frequently after five minutes and always within fifteen minutes. However, the sodium chloride enema remains ineffective when a mechanical obstruction exists. In such cases the enema is repeated after an hour and, if ineffective, surgical treatment is decided on. Thus the sodium chloride enema is also of value in the differential diagnosis. The method had not received the attention it deserves.

 *Value of Takata Reaction in Hepatic Disorders. E. Godtfredsen.—p. 131.

Takata Reaction in Hepatic Disorders.—Godtfredsen finds that a positive Takata reaction, when disorders with hyperglobulinemia, which are relatively rare, can be excluded, points to parenchymatous injury of the liver. The reaction is negative in even long-continued obstructive jaundice. In cirrhosis the reaction is positive in between 90 and 95 per cent of the cases, often in marked degree. In acute hepatitis the test is useful in prognosis, a continued negative result during the first ten days after appearance of the jaundice indicating a favorable course; conversely, a positive reaction is most often seen in cases in which the possibility of transition into chronic hepatitis (cirrhosis) is likely.

An Organized Educational Service for Interns

ARTHUR H. WELLS, M.D.

From the Department of Pathology, St. Luke's Hospital.

DULUTH, MINN.

One of the important trends in medical education today is forecast by an unusual interest and activity of medical organizations in the improvement of postgraduate training and especially of internship training. The ever increasing pressure of the American Medical Association combined with a rapidly growing interest of medical school authorities in behalf of their graduates will undoubtedly bring about widespread changes in this field of education. The growing disparity between the number of internships and the available interns for these positions is being used as an effective lever for bringing about the realization of a more extensive teaching responsibility on the part of hospital authorities.

Even as a medical school predetermines the nature of its graduates, so a hospital must plan its educational program knowing the purpose of its efforts. Internships of the general rotating type must of necessity be designed to train men for the general practice of medicine. To this end, emphasis must be placed in the fields of internal medicine, surgery, obstetrics, pediatrics and clinical pathology. To best motivate such a program, an inspiring teacher in each of these branches of medicine should be in a controlling position and assume much of the responsibility of providing a minimum of instruction in a given specialty and at the same time collaborating with the other four teaching supervisors.

It must be assumed that the intern has covered the field of didactic medicine and that he is now ready to learn how to apply himself. There is no question that this is best accomplished by his own efforts in attacking one diagnostic and therapeutic problem after another guided by the constant criticism of attending physicians. To facilitate this better in our private hospital, where it is impossible for the intern to make rounds with more than a few of the 125 staff physicians, a special "Interns' Educational Sheet" is inserted in each chart. Questions, comments and personal notations are put on this sheet including the interns' suggested

diagnostic procedures and therapy. The sheet is later removed from the chart and given to the intern. The interns are required to make routine progress notes on all patients. Furthermore, meetings are scheduled during the year at which the individual supervisors of intern instruction review many selected charts of discharged patients, criticizing the interns' notes with a free hand and at the same time making important practical observations.

A SCHEDULE OF CONFERENCES

In the majority of private hospitals and even in many teaching institutions, too much is being left to chance and the initiative of the intern. A schedule of a minimum number of talks or conferences covering applied medicine for the general practitioner should be drawn up by the supervising committee (a sample schedule is shown at the end of the article). This will not interfere in the slightest with the additional self-educational efforts of those interns endowed with sufficient interest, initiative and energy. In fact, it will stimulate the less inclined to a greater activity in the art of medicine. By concentrating pertinent subjects in the first few weeks of the internship, we hope to train good interns. After that the talks are scheduled every Monday and Tuesday at 5 p. m. Subjects directly related to his imminent entrance into general practice are concentrated mainly during the last two months. Every effort is made to avoid formal lectures. The subjects of different specialties are intermixed with the hope of teaching the student how to study diseases in the disorderly manner in which they will be presenting themselves in general practice. In a private hospital the responsibility for these many conferences is best spread widely among those members of the medical staff who are most suited for the subjects, rather than putting too great a burden on a small group. We have distributed the number of subjects in the various specialties as follows: medicine twenty-five, surgery twenty, obstetrics eleven, pediatrics six,

roentgenology ten, other specialties fifteen and miscellaneous fifteen.

Thursday evenings, throughout most of the year, are devoted to interns' clinical-pathologic conferences at which the interns rotate in presenting the more difficult diagnostic cases which they have helped study. Each case is discussed in great detail. About fifteen minutes is devoted to projecting the more important tissue sections from autopsy and surgical specimens of the preceding week on a screen with a brief comment on clinical and pathologic manifestations. Staff physicians attend these informal meetings and join in the discussions.

Each intern is scheduled to review the hospital's medical periodicals during an assigned month. Lively and stimulating comments will frequently develop between interns and staff physicians at these seminars.

The interns give case presentations at our monthly clinical-pathologic conferences before a large group of physicians. The training is valuable and even with this limited experience there is a decided improvement in the intern's ability to prepare for and speak before a formal gathering. His required attendance at monthly staff meetings not only has its scientific values but also gives him an immediate understanding of the importance of organization and cooperation with his fellow practitioners.

RATIO OF INTERNS TO ADMISSIONS

The most serious error a hospital can make is to have too few interns for the volume of work expected of them. This type of exploitation makes acceptable work impossible and stifles individual initiative. We feel that nine interns is a minimum number for our close to 7,000 hospital admissions. The Council on Medical Education and Hospitals advises one intern for every 500 admissions. On the other hand, there may be such a thing as having too many interns.

A word should be said on the importance of two features of the hospital's laboratory service in relation to intern training, a field sometimes sadly neglected. Our interns obtained permissions for necropsies on 75 per cent of the hospital deaths last year principally because of what they learned from the discussions on both clinical and pathologic aspects of each case at the autopsy table. Frequent demonstrations of practical anatomy add to the intern's dividends. Special sessions are scheduled each year for surgical technic on cadaver material demonstrated by a surgeon. The intern in the laboratory service is encouraged to replace the diener and sew up the necropsy incisions using surgical technic and materials. These practices are not intended to make surgeons out of our house officers; in fact, it is very likely that they will not be permitted to perform a single major operation during their internship.

It is fundamental to the type of medicine practiced in a hospital and therefore to the teaching of interns to remove the financial barrier of laboratory costs. A flat rate fee of from \$3 to \$5 in a hospital admitting 3,000 or more patients a year will cover all laboratory tests and will provide a service equal to that of larger medical centers for physicians, their poorest patients, and interns.

SUMMARY

Hospitals accepting the responsibility of intern training should be considered extensions of medical schools and should adapt many of their methods of teaching. Where an internship is of the general rotating type, a controlling group of teachers in the fundamental subjects of medicine, surgery, obstetrics, pediatrics and clinical pathology should arrange a schedule of conferences, seminars and medical meetings as much as a year in advance. The curriculum should stress only those subjects which will be of practical value to a general practitioner of medicine. To become a specialist in any field, three or more years of additional training is necessary. As to the numerous details of arranging a comprehensive program of this nature, there should be considerable leeway to allow for local peculiarities. However, lax methods, leaving too much to chance and the initiative of the intern, must give way to orderly, planned teaching methods, and the common practice of exploitation of interns must cease.

SCHEDULE OF REQUIRED CONFERENCES, SEMINARS AND MEDICAL MEETINGS FOR INTERNS (Time 5 to 6 p. m. unless scheduled otherwise)

- July 1. Superintendent's introduction.
Mr. James McNece
2. Introduction to surgical department; gastric decompression, hypodermoclysis, intravenous therapy, rectal tube, Miller-Abbott tube, proctoclysis, surgical dressings.
Dr. K. E. Johanson
3. Surgical technic and surgical intern; conduct of operating assistants.
Dr. T. L. Chapman
5. Miscellaneous technic: circumcisions, transfusion, spinal puncture, oxygen therapy.
Dr. Stewart Clapp
8. Introduction to obstetric department; delivery room technic.
Dr. R. J. Moe
9. Introduction to laboratory department; functions of the laboratory intern, mimeographed directions for common tests, location of apparatus and reagents.
Dr. A. H. Wells
10. Introduction to pediatric department; pediatric history, physical examination.
Dr. E. E. Barrett
11. Orthopedic apparatus and its application (demonstration).
Dr. M. H. Tibbells
12. Neurologic and psychiatric examination and history.
Dr. L. R. Gowan
15. Malpractice suits.
Mr. John J. Fee
16. Recognition and treatment of shock.
Dr. P. S. Rudie

17. Postoperative treatment in abdominal surgery.
Dr. C. H. Mead
 18. Diabetic emergencies. Dr. D. W. Wheeler
 19. Caldwell and Molloy pelvimetry.
Dr. K. E. Johnson
 22. Organic and postpartum uterine bleeding.
Dr. W. A. Coventry
 23. Treatment of burns and skin grafting.
Dr. F. J. Elias
 29. Significance of hematologic tests.
Dr. A. H. Wells
 30. Care of the premature. Dr. W. C. Martin
- Aug. 5. X-ray demonstrations of diseases of skull, mastoids and sinuses. Dr. Gage Clement
6. Anesthetics and analgesics during labor.
Dr. P. N. Bray
 12. X-ray demonstration of bone fractures.
Dr. Gage Clement
 13. Hospital medical literature review for July.
J. J. Halbert
 19. X-ray demonstration of bone tumors.
Dr. Gage Clement
 20. Stricture of esophagus and alkaline management of peptic ulcers. Dr. L. L. Merriman
 26. X-ray demonstration of diseases of stomach and esophagus. Dr. Gage Clement
 27. The hemorrhagic diseases. Dr. W. D. Coventry
- Sept. 2. X-ray demonstration of diseases of intestinal tract and gallbladder. Dr. Gage Clement
3. The acute surgical conditions of the abdomen.
Dr. L. A. Barney
 5. Interns' clinical-pathologic conference; case presentation. W. F. Vaudreuil
 9. X-ray demonstration of diseases of genito-urinary tract. Dr. Gage Clement
 10. Review of medical charts to date.
Dr. S. H. Boyer Jr.
 12. Interns' clinical-pathologic conference; case presentation. E. C. Strauss
 16. X-ray demonstration of pulmonary tuberculosis.
Dr. Gage Clement
 17. Care of the feet. Dr. R. T. Seashore
 19. Monthly clinical-pathologic conference, 7:20.
Monthly hospital medical staff meeting, 8:20.
 23. X-ray demonstration of other lung diseases.
Dr. Gage Clement
 24. Review of surgical charts to date.
Dr. K. E. Johnson
 26. Hospital medical literature review for August.
E. Emerson
 30. X-ray demonstration of diseases of the heart and mediastinum. Dr. Gage Clement
- Oct. 1. Surgical treatment of pulmonary tuberculosis.
Dr. A. Hedberg
2. Monthly pediatric-pathologic conference, 5:15.
 3. Interns' clinical-pathologic conference; case presentation. E. Steiger
 7. X-ray demonstration of miscellaneous diseases.
Dr. Gage Clement
 8. Infant feeding. Dr. O. W. Rowe
 10. Interns' clinical-pathologic conference; case presentation. D. R. Lannin
 14. Surgical anesthesia. Dr. W. A. Swedberg
 17. Monthly clinical-pathologic meeting, 7:20.
Monthly hospital medical staff meeting, 8:20.

21. Review of pediatric charts to date.
Dr. E. E. Barrett
 22. Practical suggestions on syphilis.
Dr. W. E. Hatch
 24. Interns' clinical-pathologic conference; case presentation. W. K. Hartford
 28. Dermatologic problems for general practitioners.
Dr. F. T. Becker
 29. Hypertension. Dr. S. G. Sax
 31. Hospital medical literature review for October.
William D. Cleaves
- Nov. 4. Practical suggestions on diagnosis and medical treatment of pulmonary tuberculosis.
Dr. A. T. Laird
5. Review of obstetric charts to date.
Dr. R. J. Moe
 6. Monthly pediatric-pathologic conference.
 7. Interns' clinical-pathologic conference; case presentation. J. J. Halbert
 11. Anemias. Dr. S. H. Boyer Jr.
 12. Bright's disease in practice. Dr. Stewart Clapp
 14. Interns' clinical-pathologic conference; case presentation. E. Emerson
 18. Minor surgery. Dr. G. C. MacRae
 19. Medical ethics, also the Harrison Act.
Dr. F. H. Magney
 21. Monthly clinical-pathologic conference, 7:20.
Monthly hospital medical staff meeting, 8:20.
 25. Traumatic and common eye diseases (demonstration).
Dr. M. F. Fellows
 26. Actual preparation of diabetic diet (demonstration).
Miss L. Almstrom
 28. Interns' clinical-pathologic conference; case presentation. William T. Cleaves
- Dec. 2. Actual preparation of other diets (demonstration).
Miss L. Almstrom
4. Monthly pediatric-pathologic conference.
 5. Hospital medical literature review for November.
C. Christensen
 9. Illustrated dermatologic diseases.
Dr. E. Z. Shapiro
 10. Diabetes mellitus. Dr. Richard Bardon
 12. Interns' clinical-pathologic conference; case presentation. C. Christensen
 16. Treatment of common cold and grip.
Dr. S. H. Boyer Jr.
 17. The prostatic patient. Dr. A. N. Collins
 19. Monthly clinical-pathologic conference, 7:20.
Monthly hospital medical staff meeting, 8:20.
- Jan. 6. Toxemias of pregnancy. Dr. A. O. Swenson
7. Review of medical charts to date.
Dr. S. H. Boyer Jr.
 8. Pediatric-pathologic conference, 5:15.
 9. Interns' clinical-pathologic conference; case presentation. W. F. Vaudreuil
 13. Clinical electrocardiography. Dr. R. L. Nelson
 14. Autonomic aspects of vascular balance.
Dr. R. L. Nelson
 16. Annual medical staff meeting, 7:30.

The Doctor and the Community

It is time that every physician study the social and economic forces influencing the life of his patient as well as the technical, clinical and physiologic disturbances affecting his physical and mental condition. Both react on each other. It is time that every doctor realize that he is a vital part of the community in which he lives and must play his part as a citizen in civic affairs, aiding in solving the social, economic and health problems peculiar to his particular community. If he does not do this, he should not be surprised if nonmedical persons have more influence on the health aspects of civic matters than he has. It should not be forgotten that society, not the medical profession, will ultimately determine the kind of medical service it will have. It is the duty of the medical profession to educate society so it will demand the best that medical science can offer, and this can only be done if every doctor is awakened to this larger responsibility and seizes every opportunity to enlighten both his patients and his community.—Wahl, H. R.: Community Aspects of Medicine, *J. A. Am. M. Coll.* 13: 14 (Jan.) 1938.

The Case of James

REGINALD FITZ, M.D.

BOSTON

James came to Boston from County Cork shortly after the Spanish War, as green a youngster as any greenhorn that ever left the shores of Ireland, finely built, with an engaging manner, a grand brogue and a sound knowledge of horseflesh. In some way he became acquainted with my father, and after Charles died and old Louis got run away with and smashed up the Ellis wagon—a unique vehicle that was inherited by my father from his teacher, Dr. Calvin Ellis—James became our coachman.

James and I grew to be close friends. The day that remains best fixed in my memory of him as typifying the kind of Irish unrespectability which always was part of his charm is the one at Prides Crossing, forty summers ago. He and I had manufactured a riding tandem, with the venerable gray Major in the lead—a dignified rascal with a docked tail, trained to kick with fury when his back was tickled behind the saddle—and Phyllis following. Phyllis was a docile, long-tailed, clumsy creature, never a saddle horse, usually of cowlike placidity, and a perpetual disappointment. She must have had a congenital heart lesion, for she never had any wind. She was out of Bess, my father's favorite in the days when the Ellis wagon would draw up at 18 Arlington Street early in the morning to take him off to the Massachusetts General Hospital, and by an unremembered sire recommended by one of his pupils in the class of 1882, Dr. Goss, of Lakeport, N. H. Dr. Goss and my father respected and amused each other, and between consultations, I suspect, were likely to swap tall yarns about trottin' horses and other things not strictly medical.

On the day I remember so well, James and I decided to put the tandem over a jump, and because Phyllis was clumsy we decided to give her a lesson. We constructed a 3 foot hurdle, Major in the lead, Phyllis behind with me on top of her, and James with a great stick in his hand, to do whatever might be needed in the way of coaxing. Major got over all right but Phyllis misjudged, crossed her legs when she tried to take off, turned a somersault, and tossed me through what seemed at least a 15 foot arc. That wasn't the worst of it; James and I might have kept that little contretemps a secret from the family, but Major escaped and in running home plowed up my mother's flower garden. So after that there were no more tandems or riding of horses that weren't meant to be ridden.

James and I continued friends during all the years of his life; when he went into business for himself and had a cab stand and used to drive my mother and father when they dined out, later when he bought a motor car and reliably took old ladies shopping or to the symphony and young ladies to and from the debutante balls at all hours of the night, and later still, when things didn't go so well and his business melted away and he had to work as best he could, doing odd jobs here and there in garages. He was too much the sportsman to go on relief or to accept charity, and to add to his worries by now he had a wife and a child to support.

James, besides being a friend of mine, also was my first private patient. In 1909, while I was a fourth year medical student, I was called to see him, and I can never forget the pride with which I answered the call. He lived in a boarding house in the South End, a dingy place, unattractive in every way, run by a landlady with a musty smell about her like her lodgings and cross because James was ill.

It was then that he told me of a youthful indiscretion a few years back when he had gonorrhea; and now he had rheumatism, not the amateurish kind which the modern student is likely to see but the good old-fashioned variety, so painful that when I walked into his room James complained that I hurt his knees by making the floor shake. I made the necessary arrangements and stayed with him until the ambulance came to take him to the Massachusetts General Hospital.

He was there for a month. His record is of interest, for James was feverish for three weeks, with painful, swollen joints; first the knees, later the elbows and wrists. He had leukocytosis with a count which fell gradually from 20,000 to 8,000. While he was febrile his urine contained a little albumin and a few hyaline casts, but later all signs of renal irritation disappeared. He had two positive blood cultures from which grew a diplostreptococcus without a capsule, which was slightly biscuit shaped and appeared to have the morphologic and cultural characteristics of the *Diplococcus rheumaticus* described by Poynton and Paine.¹

At that particular time, medical Boston was much interested in the work of these investigators. Poynton and Paine thought they had found an important cause of rheumatism, a diplococcus which grew in liquid mediums in streptococcus chains. In three cases they had

From the Robert Dawson Evans Memorial for Clinical Research and Preventive Medicine, Massachusetts Memorial Hospitals.

1. Poynton, F. J., and Paine, A.: The Etiology of Rheumatic Fever, *Lancet* 2: 861-869 (Sept. 22) and 932-935 (Sept. 29) 1900.

isolated the organism from the blood of patients during life, but these patients, in addition to rheumatism, were suffering from acute pericarditis. They said "We cannot claim that the diplococcus is the only cause of rheumatic fever.

Fig. 1.—Appearance of James's heart in 1937 (A) and 1939 (B): The size of the cardiac silhouette is nearly identical. Why did the heart enlarge to such an extent before 1937 and not appreciably thereafter?

That it is one cause, we believe to be proved to all practical purposes." Thus the finding of this alleged organism in two blood cultures from James appeared significant, particularly because he seemed to have neither endocarditis nor pericarditis nor any other form of rheumatic heart disease. His heart was not enlarged, nothing abnormal was heard in it beyond a faint systolic murmur, and he had no cardiac symptoms. He grew better gradually, and when it became appropriate he was discharged from the hospital with the diagnosis of infectious polyarthritis.

He got along well for the next several years, prosperously, happily and healthfully. I felt embarrassed whenever I met him, for he would give me a fine reputation and volubly tell his friends that his good health was in the main attributable to my adroitness in getting him into the best hospital in Boston quickly when he was like to die of rheumatism.

In 1918 he had an attack of influenza. How serious this was is not certain, for it was during the World War and I did not see him, but at least he claimed it was as near the death of him as could be. In 1919 he married, and in the course of time his wife had a baby who died and another who lived. It was shortly after this that all the breaks seemed to turn against him. The private livery business began to fade away and he found the financial load of raising a family a heavy one. The death of his child bothered him. He had an attack of cholecystitis and had to have an operation, and this left him with a hernia. Business went from bad to worse; he became a chronic worrier, a

disgruntled, unhappy pessimist, and he lost his Irish cheerfulness. Finally he began to get short of breath. In the spring of 1936 he said that he had been coughing all winter; now he was broken winded like old Phyllis, and his feet were swelling. He was glad to enter the Peter Bent Brigham Hospital for repairs.

In 1909, at the Massachusetts General Hospital, the left border of cardiac dulness was 11 cm. from the midsternal line and James's heart did not seem enlarged. Now the cardiac dulness seemed no greater and there were no murmurs. But the blood pressure was elevated to 200 systolic, 100 diastolic, and he was in bad congestive failure with fluid at both lung bases and peripheral edema.

He had an ominous-looking electrocardiographic tracing and a positive Wassermann test and Hinton test, but the urine, the renal function and the spinal fluid were normal and he responded well to treatment. Under rest in bed, digitalis and diuretics he lost 6 Kg. in weight in thirteen days and left the hospital much improved.

After his first break in cardiac compensation he got along fairly well for more than a year, taking life as easily as he could, avoiding hard physical labor, and constantly humiliated by being unable to support his family as he would like. In August 1937 he had to return to the hospital with uncomfortable shortness of breath and swollen ankles. The heart now appeared larger, though no murmurs were audible. The electrocardiographic tracing was as abnormal as ever, the blood pressure was high, the urine was normal and the renal function was not depressed. The blood serologic reaction was positive, though the spinal fluid again was nor-

Fig. 2.—Tracings from May 1936 to December 1939: In 1936 and 1937 there were occasional extrasystoles of both auricular and ventricular origin (not shown). The electromotive force of the heart was low. T₁ was inverted. Auricular fibrillation was first recognized in 1939. The appearance of the ventricular complexes remained essentially unchanged.

mal. Once more James responded well to treatment; during three weeks of rest he lost 8 Kg. in weight, and he finally left the hospital much improved.

The second break in compensation could not have been as incapacitating as the first, for

after it James had two years of comparative comfort; and in 1939, when he made his third trip to the Brigham Hospital, he said he came there not so uncomfortable as he had been previously but because he was on the way to

Fig. 3.—Temperature and pulse: Acute appendicitis occurred as a terminal complication of long standing congestive heart failure.

getting badly ill and experience had taught him the sense of entering a hospital early so that his stay there could be short. He had the same old complaint of increasing shortness of breath, now complicated by a sense of sternal oppression when he exerted himself.

The heart was very large, with the left border of dulness apparently 3 cm. farther from the midsternal line than it had been two years previously; the blood pressure was a trifle lower, having fallen to around 160 systolic, 100 diastolic; a moderately loud systolic murmur was audible over the precordium. The urine and renal function were normal; the Wassermann reaction had become doubtful, though the Hinton test was as definite as ever.

Two new features now were noticed. The auricles were fibrillating, but otherwise the tracing was much as it had been. During his stay a transitory attack of jaundice developed with the appearance of bile in the urine and an elevated icteric index, unassociated with cough or chest pain. This episode suggested that he might have had a small pulmonary embolus, though of this there was no definite proof. On the whole, he appeared to get along well enough and left the hospital after two weeks. Digitalis, good nursing and diuretics reduced his weight by 12 Kg. He was discharged edema free and, so far as could be told, in fairly good condition.

It soon became evident that something had occurred to make James's heart less efficient now than ever it had been before, because within a few weeks time cardiac decompensation recurred. James grew so short of breath that he was uncomfortable even at rest and, no matter how quiet he remained, edema tended to redevelop. He noticed another disturbing symptom. He suddenly began to have polydipsia and polyuria. His doctor told him that he had sugar, that he must take insulin and that he needed hospitalization.

The Brigham Hospital happened to be full at the moment but my colleague Dr. Chester Keefer was kind enough to admit James to the Evans Memorial. It was the same old story: congestive failure from a huge heart without significant murmurs and in auricular fibrillation, able to improve under bed rest, good nursing, digitalis and diuretics. On this occasion perhaps there was more evidence than previously of renal damage. The initial specimen of urine contained more albumin than heretofore, the blood nonprotein nitrogen was 45 mg. per hundred cubic centimeters, and the urinary sediment contained more casts. As the congestion cleared up, however, the albuminuria disappeared, the nonprotein nitrogen reverted toward normal and the casts disappeared, so that it seemed as if most of the renal damage was due to passive congestion rather than to any significant renal disease. The urine was found not to contain sugar, and several fasting blood sugar determinations revealed a concentration of between 120 and 140 mg. per hundred

Fig. 4.—Section through the right ventricular wall showing relatively normal coronary arteries and the diffuse nature of the myocardial fibrosis; slightly reduced from a photomicrograph with a magnification of about 25 diameters.

cubic centimeters, so that whatever diabetic tendency James had appeared to be ephemeral. The Wassermann reaction was negative, though the Hinton test was as positive as ever.

James still had a heart remarkable in its ability to recuperate from all insults. It was

notably enlarged; and while it previously produced a bad looking tracing with regular rhythm, now it continued to produce an equally bad looking tracing with fibrillation.

Yet in 1936, when compensation first broke, the circulation time was thirty-three seconds, the best vital capacity determination was 2,150 cc., and the venous pressure was 130 mm. of water. Now the circulation time was from thirty-three to forty seconds, the best vital capacity was 2,840 cc., and the venous pressure fell from 160 to 105 mm. of water under treatment. There was but little measurable evidence that his heart had grown much worse.

James's weight curve is of interest as an indicator of what his disease was doing to his general condition.

There had occurred a progressive loss in weight when he was free of edema and this, I believe, has always a significant meaning. Apparently, James was going downhill steadily in spite of whatever could be done in the way of treatment: he was drying up and withering like the leaves in the fall.

He stayed in the Evans Memorial for three weeks. He had been at home after this hospital entry for not more than a few days, when suddenly one night there developed an agonizing lower abdominal pain, unaccompanied by nausea or vomiting but preceded by slight diarrhea. He returned to the Massachusetts Memorial Hospital at once. He had slight fever, leukocytosis and localized lower abdominal tenderness. Some observers thought that there was a tender mass to be felt in the right lower quadrant. His general condition was so poor as to make any surgical procedure unwarrantable. At first he seemed to get the best of his troubles, but later his temperature became subnormal and he sank rapidly.

Those who saw him felt that he had either acute appendicitis or thrombosis of a mesenteric vessel. To me it is a queer twist of fate that made my father's old coachman, my first patient and a man whose case I had followed for thirty years, die at the age of 62 as the result of acute appendicitis, a disease that had always so much interested his former employer.

NECROPSY

The necropsy was performed by Dr. Charles F. Branch, of Boston University, who furnished a detailed account of his various observations:

In the region of the appendix at the lower end of the right lateral gutter, just at the pelvis brim, were several coils of small intestine firmly matted together by partially organized fibrinous adhesions. These formed the roof of a well localized pelvic abscess which contained approximately 50 cc. of thick creamy foul-smelling purulent material. The appendix was found lying in the upper lateral wall of this abscess cavity. It was approximately 6 cm. in length. Its proximal four fifths averaged 6 mm. in diameter, while its tip was distended to approximately 1 cm. in diam-

eter. The tip was represented by a grayish green slough, from which there was a perforation into the abscess cavity. The proximal portion of the appendix showed relatively little gross pathologic change.

Microscopic examination of the appendix showed its lumen to be filled with neutrophils and the mucosa to be intact except in the region of the tip, at which point the entire appendix was represented by a sloughed gangrenous mass of tissue. The vessels of the serosa were engorged, but the smaller arterioles showed no specific pathologic alteration or occlusion.

The heart weighed 640 Gm. It was firm and contracted. The myocardium was hypertrophied and non-friable. The right ventricle was especially large, measuring 1 cm. in thickness. There were a few small scattered areas of fibrosis to be seen throughout the muscle, none of which measured more than 5 mm. in diameter.

The right auricle was dilated, measuring approximately 10 cm. in diameter when fully distended. The right auricular appendage was occluded by an oval thrombotic mass which was firmly attached at the auricular tip. The left auricular appendage also was occluded by a similar though slightly larger mass; this was much softer and more friable and showed extensive central liquefaction.

There was no endocarditis. The tricuspid and pulmonary valves were normal except for a slight increase in their measurements. The base of the mitral and aortic cusps showed an advanced degree of arteriosclerosis. The mitral commissure showed a semilunar sclerotic plaque approximately 3 cm. in width and 1.5 cm. in depth which was in immediate apposition to the aortic base. The commissures of the aortic cusps were firmly fused for a distance of from 5 to 7 mm. and showed considerable calcification.

Hospital Weight Measurements in the Case of James

Date	Weight at Entry (Kg.)	Weight at Discharge (Kg.)
May 1936.....	88.4	82.4
August 1937.....	88.8	81.0
July 1939.....	86.5	74.6
November 1939...	79.5+	71.8

The coronary arteries were patent but showed numerous points of narrowing due to calcified atheromatous plaques. There were extensive stretches of coronary vessel, however, which showed no gross intimal damage.

Microscopic examination through various portions of the heart, including sections from the right and left ventricles, the interventricular septum and the auricles, all showed a peculiar fibrosis, much more noticeable microscopically than to gross examination. In general, the muscle bundles stained normally, showed their cross striations to be well preserved, and only in rare instances hydropic degeneration. The presented any evidence of hydropic degeneration. The increase of connective tissue throughout the myocardium presented surprisingly little pathologic change indicative of any specific cause other than that customarily associated with simple coronary occlusion. No Aschoff bodies were observed in the several sections examined. An occasional area of diffuse infiltration with small numbers of lymphocytes was the most prominent feature observed, and this was more marked beneath the pericardium than elsewhere. Here the clumps of lymphocytes tended to be arranged around blood vessels.

The arterioles throughout the heart showed varying degrees of atheromatous degeneration; however, no occlusive lesions could be demonstrated.

The aorta showed advanced atheromatous degeneration throughout its entire course, with extensive plaques of calcification in the abdominal portion.

Fig. 5.—Section through the interventricular septum showing in greater detail the diffuse fibrosis; reduced from a photomicrograph with a magnification of about 250 diameters.

Many of these formed shale-like excrescences protruding into the lumen. About the margins of such lesions were typical old atheromatous ulcers. Throughout the thoracic portion of the aorta were several areas of white fibrous thickening of the intima, accompanied by many closely set linear puckeringings presenting the characteristic "tree bark" appearance of syphilitic aortitis.

Microscopic examination of the thoracic aorta showed a marked fibrous and hyaline thickening of the intima beneath which were extensive deposits of atheromatous debris, cholesterol crystals and fat laden macrophages. The internal elastic membrane was badly distorted and ruptured at several points. The media showed numerous areas of scarring and many areas of perivascular fibrosis infiltrated with plasma cells and lymphocytes. The vessels of the adventitia showed similar perivascular infiltration.

The heart obviously was badly damaged by a diffuse and fairly uniform fibrosis which was not at all characteristic of healed rheumatic fever or of a possible gonococcal infection or altogether characteristic of simple arteriosclerosis. The degree of coronary sclerosis did not appear commensurate with the diffuse myocardial fibrosis at hand. The picture in the upper aorta was compatible with the diagnosis of syphilis. Dr. Branch suspects that the myocarditis was of syphilitic origin, though he is not certain. He raises another interesting suggestion: Could the diffuse myocardial fibrosis be the end result of successive bouts of interstitial edema and be due fundamentally to lack of vitamin B—an atypical beriberi heart?

The lungs were noteworthy in that the larger arteries throughout each lobe showed large numbers of soft raised atheromatous plaques which partially occluded many vessels. The degree of gross pulmonary arteriosclerosis was considerably more marked than is usual in an individual of the patient's age. No evidence of pulmonary embolism was discoverable.

On microscopic examination the bronchi were well preserved, although the musculature of the larger bronchioles was distinctly thin and atrophic. Occasional peribronchial arterioles showed edema of their walls and definite infiltration with lymphocytes and endothelial cells. The larger arterioles tended to show an edematous, myxomatous appearance of their media and adventitia, with numerous patches of atheromatous degeneration of their intima. No completely occlusive lesions were found, although many of the smaller arterioles were distinctly narrowed. In general the alveoli were either emphysematous or atelectatic, with definite diminution of elastic tissue in the interalveolar walls and containing varying numbers of hemosiderin laden macrophages. There was nothing in the picture suggestive of Ayerza's disease, nor were there any microscopic lesions compatible with the degree of arteriosclerosis noted grossly. On the whole, the histologic picture was that of long standing chronic passive congestion.

The kidneys weighed 430 Gm. On section, the normal relationship between the pyramids and the cortex was well defined, the latter measuring 8 mm. in width. The capsule stripped with some difficulty, leaving a finely granular, deeply pitted, bright reddish brown surface on which the capillary network stood out sharply. There was a moderate amount of pelvic fat. The pelvic epithelium and ureters were normal. The renal arteries showed a marked degree of arteriosclerosis throughout their entire length. There was no gross evidence of frank obstruction due to kinking or atheromatous plaques.

Sections through various portions showed certain subcapsular areas in which the glomeruli were sclerosed and the tubules were atrophic or absent and where the relative increase of connective tissue was infiltrated with small numbers of lymphocytes. In general, however, the glomeruli were in remarkably good condition, and their afferent and efferent arterioles stood out sharply as normal appearing vascular entities. The tubules were relatively normal in appearance, the epithelium being intact and the lumens containing but a small amount of amorphous coagulum. The capillaries were markedly engorged. Pathologically, the kidneys showed no marked degree of vascular nephritis; it is not remarkable that the renal function remained so normal.

Fig. 6.—Section of pancreas: There is considerable fibrosis and hyalinization of the islands of Langerhans; reduced from a photomicrograph with a magnification of about 250 diameters.

The pancreas weighed 80 Gm. Grossly it appeared normal. Histologically the appearance was that of diabetes. There was a moderate general increase of connective tissue throughout, with moderate numbers of increased fatty trabeculae. In many places the connective tissue was infiltrated with small numbers of lymphocytes and plasma cells. The majority of the islands of Langerhans showed some degree of hyalini-

zation varying from partial replacement of one or two cords to almost complete fibrosis of the entire unit. The arterioles everywhere showed a marked fibrous and hyaline thickening of their intima, in places amounting to complete occlusion.

The ductular epithelium at occasional points showed definite evidence of metaplasia. This, Dr. Branch believes, was probably due to vitamin C deficiency.

Fig. 7.—One of the pancreatic ducts showing epithelial metaplasia; reduced from a photomicrograph with a magnification of about 100 diameters.

The other organs showed no significant changes beyond such as were compatible with long standing chronic passive congestion.

COMMENT

I have reported the case of James at length because it is interesting from many points of view. Here was a man who, during thirty years of adult living, went through a variety of vicissitudes almost entirely under the eye of one doctor: gonorrhea and unrecognized syphilis; an attack of rheumatism with positive blood culture; a period of strenuous living, including hard work and a great deal of exposure to bad weather and long hours; an attack of influenza; a major surgical operation; a period of unhappiness and worry; dire poverty; a prolonged sense of frustration because his later years were so different from what he hoped they might be. From all this chain of circumstances there developed hypertension, a badly diseased heart without clinical evidence of valvular disease, probably diabetes, surely syphilitic aortitis and much generalized arteriosclerosis.

One might argue that the necropsy in the case of James was useless, that the prognosis was plain at the time of his first decompensation, that it made no difference whether, at the end, he had mesenteric thrombosis or appendicitis, because there was nothing to do about either, and that the diagnosis was evident long before his death, clearly labeling him as being nothing more than just another cardiorenal-vascular patient.

On the other hand, cardiorenal-vascular disease is today one of the most important pathologic entities, about which very little is known. What made James have vascular disease at all? How did he escape rheumatic heart disease?

How much of a part which might have been prevented did syphilis play in the illness? Why did high blood pressure develop? Why did he not have angina pectoris? Why did he escape renal insufficiency? Why did he have so striking a degree of right ventricular hypertrophy? Why did his heart hypertrophy so greatly? What made a positive Wassermann test become doubtfully positive and finally negative without any treatment? What part did other infections than syphilis play in the breakdown of his health—or hard work, or exposure to all kinds of weather, or unhappiness, or avitaminosis from faulty diet due to poverty? Why did auricular fibrillation develop and how did this affect the function of his heart? With marked pancreatic lesions supposedly characteristic of diabetes, why did not clearcut signs and symptoms of this disease develop? Why did he have appendicitis? All these questions, and many others, come to mind when the case of James is studied in its entirety.

My own idea is that such questions can never be answered satisfactorily until the life cycle of a large group of individuals like James is studied. A great many cases like that of James must be followed medically during the entire lifetime, must be examined at the end by a pathologist and must be reported in readable fashion. In due course of time, by such means, information can be assembled which may be of great importance. At present great emphasis in clinical investigation is likely to be placed

Fig. 8.—A comparison in necropsy percentage: The dotted curve represents the necropsy percentage in 536 hospitals approved for intern training in 1926 (*THE JOURNAL*, March 30, 1929, p. 1036). The solid curve represents the necropsy percentage in 729 hospitals approved for intern training in 1939 (*Ibid.*, Aug. 26, 1939, p. 832). To make the figures comparable, each curve has been plotted on the basis of a thousand hospitals.

on short term physiologic or chemical research and but little on the more time consuming, more elusive study of man as a whole. This is only natural because a young man at the commencement of his career wishes immediate results

with immediate publication and is unlikely to be patient at starting on a problem which he knows can never be finished during his lifetime. Hospitals, however, can do more than they now are doing to help in the accumulation of carefully documented experience regarding the life history of human disease observed over a long period of time.

A chart constructed from data published from time to time in the educational or hospital numbers of *THE JOURNAL* yields significant information.

Even in the hospitals approved for intern training there still is evident too much inertia regarding careful clinical and pathologic correlation. While notable progress has been made in the last thirteen years, owing largely to the efforts of the Council on Medical Education and Hospitals, the percentage of necropsies to deaths in many hospitals should be higher than it is at present. That a necropsy percentage of over 70 is possible was demonstrated last year in twenty-seven institutions, and that a remarkable general renaissance is being stimulated in the

attitude of hospitals toward the importance of pathology to clinical medicine is very apparent. Those hospitals with the best records in clinical-pathologic correlation are mainly government hospitals or teaching hospitals intimately connected with medical schools. All hospitals which train interns are teaching hospitals. Each staff member of any of these hospitals must constantly remember that he is a teacher and remind himself, in his capacity as preceptor, that his interns will imitate him for the rest of their days. He must teach them in diagnosis and treatment that the complete understanding of the individual patient is of paramount importance.

The ultimate duty of a decent doctor to his patient is to bring to light discrepancies between clinical and pathologic data. It is by this method that mistakes are discovered and that important advances in the knowledge of man and his reactions to disease and environment are still to be made.

319 Longwood Avenue.

Personal Problems and Attitudes of Medical Students

NORMAN R. FIELDER, M.A.

Program Director, West Side Professional Schools Department, Y. M. C. A.
CHICAGO

A widespread interest in this work was indicated by the responses received from the first surveys published in the Student Section of *THE JOURNAL*, Nov. 25, 1939, and the results of last year's clinics. Sixteen leading medical schools and several other educational institutions in different states have asked for additional information. Some have expressed a desire to cooperate further. Many practicing physicians have responded favorably.

The 1940 Medical Students Problems Clinics were characterized by the extension of the personal problems survey to include a larger number of students, the widening of the scope of the clinics to include many hitherto unsolved social and personal problems of students, and a growing interest on the part of faculty and students.

ORIGIN OF THE CLINICS

The present clinics are an outgrowth of a project instituted three years ago by the Inter-Medical Schools Student Council of the West Side Medical Center in Chicago, following addresses by Dr. Harry A. Overstreet, head of the Department of Psychology and Philosophy

of the College of the City of New York; Dr. Morris Fishbein, Editor of *THE JOURNAL*; Dr. David J. Davis, dean of the University of Illinois College of Medicine; Dr. T. T. Job, Loyola University School of Medicine; Dr. F. L. Lederer, University of Illinois College of Medicine; Dr. G. E. Wakerlin, University of Illinois College of Medicine; Dr. G. B. Hassin, University of Illinois College of Medicine; Dr. Arthur H. Compton, scientist, University of Chicago, and other outstanding leaders in the field of education and medical practice. Interest in personal problems of students began to crystallize. After many consultations with teachers and practitioners including Drs. H. M. Sheaff, and A. E. Diggs of the University of Illinois College, Drs. William H. Welker and Bernard Fantus of the University of Illinois College of Medicine, Dr. Noyes, dean, University of Illinois Dental College, and Dr. McNulty, Chicago College of Dental Surgery, and others, the first clinics were developed. Each clinic has been under the leadership of a commission consisting of several students and one or more faculty members.

In 1940 more than 3,500 students who were enrolled in the different schools located in the Chicago area participated in the study.

This year's Medical Students Personal Problems Clinics were developed around the basic areas of student concern emerging from the experience of the past three years. The resolu-

Much credit is due to the administrations of the schools who gave permission for the studies in their institutions. Also, cooperation was shown by the many faculty members, who gave consent for students conducting the survey to appear before classes. Distribution of the questionnaire to so many people would have been impossible if it had not been for the help and teamwork of a large number of interested students who helped in the drafting of the questions. Many gave freely of their time and efforts in the circulating and collecting of returns.

tion on medical education adopted in Kansas City at the eighty-seventh annual session of the American Medical Association continued to serve as a guiding influence.

The specific problems were determined by a questionnaire and through an exhaustive analysis of student situations and personal problems. Other general problems were drawn out of the common interest and daily activities of students now engaged in attending medical schools.

Underlying the entire procedure was recognition of the requirement that the student shall be thoroughly prepared to take his place in society both as a citizen and as a skilled practitioner and community leader with the understanding and ability necessary to meet the basic problems. In brief, the fundamental problems of satisfactory living were the goals sought in the clinics.

METHODS OF PROCEDURE

Since the field covered by this project had never been surveyed by a similar type group, it was necessary to develop most careful methods of procedure. All information received was carefully tabulated and every step checked. When the information was finally compiled it enabled the investigators to compare the latest results with the earlier observations.

From the beginning the leaders were agreed that the project should be shorn of undesirable approaches and that the methods of the clinics must be to employ the technics of the modern laboratory in an exacting examination of the personal and social problems confronting the medical student. On the assumption that individual development takes place best when efforts are directed by clear purposes and reliable information, the program was presented around those important problems determined by analysis of situations which confront every student and faculty member in the medical school.

Medical students live a strenuous life in a constantly changing world. No one is spared the struggle to make adjustments to new conditions. Disastrous social conflicts are to be found among those who cannot adjust themselves to new conditions.

Unsatisfactory living on the part of the individual is a direct result of inability to harmonize with one's environment. The task of training for the medical profession is inseparably related to the broader field of adult education and includes community activities and other social pursuits. It is an indispensable factor in advancing social and professional standards that the future medical man acquire these broader skills in conjunction with the technical professional training.

THE QUESTIONNAIRE

To secure a proper setting for the discussions of the clinics and to provide a source of valid

information, the following questionnaire was devised and used by the students:

Please Do Not Sign Your Name! Your help is requested in gathering information regarding what medical students do and think. The answers to the questions, when compiled, will provide a substantial basis for the discussions of the Medical Students' Problems Clinics. Please be honest. In no way will there be any attempt made to identify you with your answers.

Q.—Sex? Q.—Age? A.—Average 26. Q.—Married? Single? Divorced? School? Year? Religion? Race?

1. Q.—Do you feel that you personally are in need of more cultural training and background to equip you for the practice of your profession? A.—Yes 63%, no 37%.

2. Q.—Do you use alcohol? A.—Moderately 70%, not at all 20%, excessively 10%.

3. Q.—Which of the following have you attended more than three times during the school year? A.—Opera 3%, plays 6%, movies 25%, church 10%, concerts 9%, athletic activities 12%, read nontechnical books 12%, night clubs 9%, taverns 9%, burlesque shows 1%, gambling "joints" 2%, lectures (not required). 4. Q.—How do you prefer to attend these? A.—Alone 14%, with your own sex 30%, with the opposite sex 56%.

5. Q.—Do you have a college degree? A.—Yes 65%, no 35%.

6. Q.—Do you intend to specialize in a branch of your profession which requires further study after you have completed your present course? A.—Yes 53%, no 47%.

7. Q.—Roughly what percentage of your courses do you consider time wasted? A.—25%.

8. Q.—Does the curriculum leave you enough time for social interaction and enough leisure to pursue other interests? A.—Yes 59%, no 41%.

9. Q.—Roughly what percentage of your instructors do you consider good teachers? A.—50%.

10. Q.—Do you depend on religion for personal satisfaction? A.—Yes 37%, no 63%.

11. Q.—How do you attend church or religious meetings? A.—Regularly 7%, occasionally 10%, never 83%. Q.—If you do not attend regularly, why? A.—Work 10%, sleep 75%, indifference 15%, fear of ridicule 0%.

12. Q.—Since entering professional training, how has your regard changed toward the church? A.—Greater belief 30%, less belief 70%.

13. Q.—Regardless of financial status of the student at what time during his training is marriage advisable? A.—First two years 18%, last two years 25%, internship 27%, "starvation period" 30%.

14. Q.—Compared with your intellectual level, what sort of person would you prefer to marry? A.—Below 0%, even with 74%, above 26%.

15. Q.—Do you approve of women physicians? A.—Yes 27%, no 73%. Q.—If any of your family were ill, would you call a woman physician? A.—Yes 38%, no 62%.

16. Q.—Do you approve of girls sharing expenses on dates? A.—Yes 76%, no 24%.

17. Q.—In a word, what do you regard as the most undesirable characteristic in students of your school? A.—First selfishness, second egotism, third rudeness, fourth cheating.

18. Q.—Have you ever had a venereal disease? A.—Yes 3%, no 97%. Q.—Indulged in sexual intercourse before marriage? A.—Yes 60%, no 40%. Q.—Indulged in sexual intercourse when engaged? A.—Yes 72%, no 28%.

19. Q.—Do you use contraceptives personally? A.—Yes 85%, no 15%. Q.—Do you favor their use by the lay public? A.—Yes 89%, no 11%. Q.—Do you think the doctor should be trained to give this information? A.—Yes 97%, no 3%.

20. Q.—Where do you plan to practice? A.—In a large city 79%, small community 21%.

21. Q.—How is your physical condition and health as compared to how it was when you entered the professional school? A.—Same 65%, worse 35%.

22. Q.—Have your moral attitudes changed since being in training? A.—More critical 27%, more lax 73%.

23. Q.—Do you understand the Wagner bill? A.—Yes 46%, no 54%.

24. Q.—If the United States declared war for any reason would you volunteer for military service? A.—Yes 25%, no 75%.

25. Q.—Are the students in dentistry, medicine, pharmacy and nursing professions more careless than the average in dress? A.—Yes 57%, no 43%.

26. Q.—Is a professional student justified in accepting financial support from his wife? A.—Yes 72%, no 28%.

27. Q.—Do you feel that your profession has hardened you to human need? A.—Yes 36%, no 64%.

28. Q.—Do you favor some college training for admission to nursing school? A.—Yes 100%. Q.—If so, how many years? A.—Average two years. Q.—To medical school? A.—Average three years. Q.—To dental school? A.—Two years. Q.—To pharmacy school? A.—Two years.

29. Q.—During your professional training how has your belief in a personal god become? A.—More important 32%, less important 68%.

30. Q.—Do you consider your professional school colleagues adequately schooled in etiquette? A.—Yes 40%, no 60%.

31. Q.—Do you feel that your professional training tends to make you humble? A.—Yes 30%, no 70%.

32. Q.—Are you influenced by propaganda? A.—Yes 51%, no 46%.

33. Q.—Do you believe in regimentation of your profession? A.—Yes 3%, no 97%.

34. Q.—Do you favor your school establishing certain standards for living conditions? A.—Yes 52%, no 48%.

The results of this clinical analysis show trends of thought and points of view growing out of a sincere attempt by students to face their personal problems.

COMMENT ON QUESTIONS

Questions 1, 3, 25 and 30: Investigation of these questions reveals that many cultural interests are suffering from anemia among medical students. Many an eminent educator, scientist and medical leader, brought to the field by the various schools, addresses a distressingly small audience. Recitals and concerts in the neighborhood institutions are usually attended by a small number. Neighborhood movies featuring love thrillers boast the best attendance of any institution in the whole area. In the field of current reading it is interesting to note that students buy fifty copies of *Esquire*, *True Romance* and *Detective Stories* to one copy of the *Atlantic* or *Harper's*. The only places where students go *en masse* are to required class lectures, clinical demonstrations, the movies and dances. As a matter of fact, the average medical student is not concerned with the cultural aspects of the usual uplift program planned for him. And naturally so! The medical school is a world of physical facts, clinics, dissecting rooms, microscopes, test tubes, case histories, examinations and books.

Question 8: This question seemed to include more than the curriculum—the whole scope of the daily activities seemed to be involved. Careful examination of student life inevitably takes one outside the walls of the institution responsible for the formal technical training program. Here we find that certain aspects of our twentieth century civilization draw students away from that phase of life usually called intellectual and religious. The speed of life, with radios, newspapers, crowded schedules, restlessness, fast moving crowds hurrying to go no place, all tend to induce hastiness in mental activities, which in turn breeds superficiality. With little chance to concentrate on any single field of thought, students tend to jump from one interest to another.

Question 11: Religion, as a subject for serious intellectual concern, is not popular among the great majority. It is rarely a subject for serious study and the students are conspicuously absent from services of worship conducted by churches within the community. Attendance at church services both regularly and occasionally is participated in by only 17 per cent. A breakdown of the 17 per cent attendance figure opens the way to many interesting speculations concerning the carry over results of early childhood training methods practiced by the various faiths and denominations. Of those reported as regular or occasional church attendants the nonmember of any church group ranked first with 7 per cent. Strange as this appears, on careful study it

seems to substantiate the often repeated statement of students that early church going experiences, when reviewed during their professional training period, appear unattractive and unsatisfying for the scientifically trained mind. Of the remaining group, Lutherans come second with 5 per cent, Catholic students were third with 3 per cent, Baptist and Jewish come fourth and Methodists last. A fact of tremendous importance growing out of this phase of the study is that the church has not yet found a way to attract and to hold the large body of highly trained young men and women who will become our influential professional leaders of tomorrow. Can the church build a program that will grip the interest and command the loyalties of these youth?

Questions 10 and 12: One of the most interesting facts revealed by the study of these questions is that the students of all different faiths are proportionately indifferent to the church. There seems to be no doubt about it. The church for most of the students is simply not counted. It is true that some talk about it, but much as if it were a dead thing. "Jam sessions" turn to it occasionally, but their talk for the most part lacks genuine interest.

Question 18: It is recognized that there are grave dangers in premarital sexual intercourse. The social attitudes and restrictions at this point are so strong that they may be reflected in the attitudes of the two toward themselves and toward each other, even though intellectually they believe that their action is quite proper. Unintended pregnancy is a further possible source of complication. For some it is well to make a distinction between gratification and satisfaction. By gratification is meant the gaining of temporary pleasurable sensations. By satisfaction is meant the achievement, in addition to gratification, of friendship, love, beauty and all those distinctively human values which make life worth while. Certain types of sex gratifications which relieve tension and give pleasurable sensations at the time do not satisfy the complex, interrelated needs of a civilized man or woman. It is of first importance to discover how to handle sex desires so as not only to gratify but also to satisfy a cultivated person.

Question 21: It is now generally recognized that tuberculosis constitutes the main occupational hazard of the medical student. This danger is probably increased for students who are forced to work their way through the professional school. Rest with proper exercise and adequate recreation are absolute essentials in the life of students. The administrations of the schools are increasingly developing greater means of safeguarding the health of the student.

Question 22: This attempt to look facts in the face possibly has brought to some the conclusion that it's hopeless, that nothing much

can be accomplished in changing student moral attitudes for the better; medical students will go on being what they are and we cannot improve them. Such conclusions might be justified if we continue to follow the paths of old. Careful study of the customary practices of the past and the accompanying failures to make progress bring to light the fact that most of the basic principles in sound education and the essential conditions for proper cultural development have been grossly ignored. Medical students resent pressure. "Religion is my own business" is the usual reply when an overzealous worker speaks of spiritual matters.

Question 29: The results of an earlier survey were compared with the recent results, and it is significant to note that 98 per cent of the freshmen believe in God while 53 per cent of the seniors indicate disbelief in God. If these statistics indicate what takes place among students in general, it would appear that the concept of God gained by many in early youth cannot stand up under the microscopic test of a scientific training for a profession.

Question 29: It is the sincere belief of those interested in the final results of this study that the only work that promises anything worth while in the developing of personality and influencing character with medical students must be based on the spirit of science at its best, which means the uncommercialized love of truth no matter where it leads, sincere effort and eager curiosity, readiness to discard yesterday's theories in the face of newly acquired information, endless explorations built on an unquestioned belief in life.

CONCLUSION

Leaders in the medical profession more and more are stressing the fact that the task of the physician is the most intimate and delicate in the field of public service. As soon as the student really grasps the significance of this fact he will begin to see that his professional training of necessity must include and strive to develop the social and cultural aspects of human relations.

From the view of the faculty and administrations of the training institutions the selection of prospective students will increasingly be based on more than scholastic standing, as indicated by the following resolution at the Eighty-Seventh annual session of the American Medical Association:

WHEREAS, The relationship between physician and patient embodies many factors that must be considered in the determination of an individual's fitness to be a doctor of medicine; and

WHEREAS, The entrance requirements to the degree of Doctor of Medicine cannot be evaluated on a strictly academic basis; therefore be it

Resolved, That the following factors be considered in the selection of students who are to become doctors: character, personality, social fitness, adaptability and motivations.

Gradually the medical schools are providing new opportunities for progressive enhancement and development of personalities of students to go along with the study of anatomy, physiology, chemistry and surgery. To prove the necessity of correlating those qualities included in the American Medical Association resolution—motivation, adaptability, social fitness, character and personality—with the technical and professional knowledge, place that physician beside the beds of sick human beings, where he must deal as much with human nature as he does with medical and professional technics. Thus it would seem that a prerequisite to graduation from a medical school would be a properly balanced personality.

How can we test the personality of a student to find whether he has the characteristics desirable in a practitioner? How are we to apply tests to determine whether a student is socially fit for the profession? These questions have been discussed in the clinic sessions by students from the various schools. The results of the questionnaire were used as a foundation.

It was agreed that one of the best ways to test each applicant for entrance to a medical school would be to find out what he has been in the past several years. Ask teachers in high school and the undergraduate colleges to keep records of students. Following are some questions that might provide essential information:

Personality.—1. What sort of a mask does he wear?

2. Does he mingle easily with his fellows?
3. Does he have many friends?
4. Has he any traits that make a student unable to get along with his associates?
5. Is he conceited?
6. Is he unclean in personal habits?
7. Is he undependable?
8. Is he excessively stubborn?
9. Is he quarrelsome?

Social Fitness.—1. Is he able to get along with others or is he cantankerous?

2. Is he upright or is he underhanded?
3. Does he have control of his emotions or is he uncontrolled?

Character.—1. Is he honest?

2. Has he ever been found guilty of any dishonesty?

Adaptability.—1. Has he traits which make him effective among his associates?

2. Has he held class positions?
3. Has he shown social snobbishness?
4. Has he been a decided recluse?
5. To what extent has he taken part in social activities?

Recreation.—1. Is he active in sports?

2. Does he take active part in recreations?

3. Does he sit back and observe rather than participate?

Motivations.—1. Was his motive in entering professional schools: (a) Prestige? (b) Ego-centric? (c) Easy way to make money? (d) Sense of human service? (e) Having something grand to do?

2. Has he shown an interest in something other than grades?

3. Does he go out of his way to do things for others?

4. Does he devote time and interest to others than himself?

1804 West Congress Street.

Comments and Reviews

A MEDICAL CENTENNIAL OUTLOOK

Condensation of an address by Dr. James Ewing, New York, delivered at the one hundredth anniversary of Albany Medical College, June 12, 1939, and published in Albany Medical Annals, December 1939.

Centennial celebrations of medical schools are rare opportunities when we may review the long past, trace the forces which have directed the fortunes of the institution, acknowledge our debt to the several generations of strong men who have served their alma mater, and renew our allegiance to the traditions which experience has proved to be sound. The present occasion is especially notable because Union University and the Albany Medical School have a distinctive local significance and belong to that group of institutions which are peculiar to our American educational system, the smaller colleges.

Many educators think they detect in the smaller colleges certain advantages and refinements which it is difficult to preserve in the highest degree in the great universities. They seem to consist in the comparative simplicity of college life, the more friendly contacts between students and the more intimate relations with teachers. One must suspect that the smaller college is able to respect established traditions and not to yield so readily to passing popular demand for untried innovations. High scholarship, mental discipline and character building are delicate plants easily crowded out by the influx of more modern and more practical pursuits. The college graduate from the great universities is probably better fitted to make his way in the world, but the man from the small college often seems to have deeper roots and is designed to go further, at least in certain worthy directions. There is every reason to urge that the smaller colleges should maintain their unique position in our educational scheme, for many regard them as the beauty spots of our intellectual world.

CULTURAL VALUE OF MEDICAL STUDY

Medicine is still the mother of the sciences. Contact with the medical sciences has a powerful and a peculiar cultural influence not shared by any other intellectual pursuit. Every university needs a medical school to lend

earnestness and incentive to the pursuit of pure science and higher learning. It is the significant nature of medical knowledge and its intimate relation to human values that lends to the study of medicine its peculiar cultural value. The study of medicine enables a man to follow Agassiz's advice "Know thyself." Without that knowledge it must be questioned whether any man can consider himself really educated. There is an astonishing naiveté regarding the conceptions of the average educated lawyer, clergyman and business man, not to mention the general public, about his bodily sensations and functions, his position in the biologic world, in fact his true significance as an individual, and this ignorance colors his judgments in many of the relations of life. The ancient mysticism about medicine still prevails and the medicine man still circulates freely in polite society. In a medically educated public the medical cults would not thrive. In the medical sciences the penalties visited on the adventurer and false prophet are drastic and destructive, but when medicine becomes mixed with politics the medical politician may survive several false projects merely by repeating them on a larger scale at the expense of the taxpayer, but only because there is no informed body of public opinion. There is a great need of expansion of elementary medical knowledge with the general public and of that culture and balanced judgment which goes with such knowledge, and the pervading influence of the medical department of the universities seems to be the sole source of such help.

FORESIGHT OF THE FOUNDERS

The history of Albany Medical College reveals a unique record of farsighted vision and heroic devotion on the part of its founders. Dr. Alden March came to Albany from Massachusetts in 1820, when the city had 15,000 inhabitants, and started a course in anatomy with fourteen students. In 1825 he was appointed professor of anatomy in the Vermont Academy of Medicine at Castleton, where he remained until 1830, when his Albany class had grown to thirty students. In 1831 Dr. James H. Armsby joined him in Albany and the two physicians worked together to found a medical college. They gave public anatomic demonstrations to a selected

group of laymen and they secured the solid support of influential citizens, who contributed the first funds for the founding of a medical school. This was a very early period in the growth of public medical intelligence for physicians to submit their interests to a group of laymen.

It has often been said that every successful pioneer institution is but the shadow of some man. In this instance that man was Dr. Alden March. In Philadelphia it was Dr. William Shippen. In Boston it was Dr. John Warren and, at Dartmouth, Dr. Nathan Smith.

Another versatile figure, Dr. James H. Armsby, joined with Dr. March in his early efforts and seems to have contributed essentially to their success. Dr. Armsby had a remarkable gift for enlisting the support of the public and in obtaining money for the school. His interests were wide, including no less a project than the founding of a well rounded university in the city of Albany.

FORECASTING THE FUTURE FROM THE PAST

Looking backward, we are privileged to acknowledge the debt which Albany Medical College and the city of Albany owe to these strong men. What does this centennial retrospect teach for the future of medicine?

The great achievement of the past century has been the virtual control of infectious diseases and, as a result, the average expectation of life has been increased about twenty-five years and the age composition of the population correspondingly raised. Recently this line of progress has been greatly forwarded and consolidated by the discovery of chemical agents which seem able to control to a large extent the ravages of the two most formidable bacterial causes of disease, the streptococcus and the pneumococcus. It seems reasonable to expect that these epoch making discoveries in chemotherapy may be extended even further and as a result that medicine in the future will be forced to turn its main attention to the nutritional and degenerative diseases, including especially mental deterioration, cardiorenal disease, cancer and diabetes. Thus medical problems of the future loom quite as large and appear far more complex than those which occupied physicians a hundred years ago.

A MENACE TO MEDICINE

Political and economic problems face the medicine of the future as never before in its history. Political and economic changes have radically altered the complexion of German medicine, which is not likely to regain the zenith reached about the beginning of this century. Somewhat similar limitations are beginning to appear in other European countries, and it is not safe to assume that America is immune to such forces. With us the danger lies in the lack

of understanding between the public and the medical profession. The public does not and apparently can not understand the implications of disease, the vast scope and variety of bodily disorder, and the limitations of curative medicine. I believe that the lack of mutual understanding between the public and the medical profession is greater today than it was thirty years ago. The causes seem to be traceable to the greater control of curable infectious diseases and many minor disorders, and the greater incidence of the more chronic incurable diseases, for which the individual himself is mainly responsible. An important factor is also found in the decline of public morals and the sense of individual responsibility and self help. When great masses of people receive the dole, it is an easy way to assume that some one can hand out relief from disease in the same lavish manner as the government hands out money. The American public will sometime learn that it is a long way from easy money to freedom from disease. Yet certain medical authorities, some occupying positions of importance, chiefly in institutions, but not very familiar with the conditions of medical practice, not overmindful of the social significance of disease and wholly neglectful of the weakness of human nature, have assumed that by the expenditure of vast sums of money it will be possible to improve greatly the care of the sick poor and largely meet the demands of the public. The great majority of thoughtful physicians regard this project as chimerical and some, myself among them, regard it as a grave menace to the future of American medicine.

The idea that this vast sum administered by men and women who mostly lack a record of practical achievement, but are animated by the naive spirit of the big brother, can be wisely expended in a relatively brief time is unreasonable. The scheme is a utopian project designed for an ideal community. It may be suggested that in an ideal community such need would not exist. Among the many hazards inherent in this scheme, one may refer merely to the fact that the withdrawal of such a vast sum from the taxpayers will seriously aggravate the present decline in the resources of American universities and transfer to a group of relatively inexperienced governmental bureaus virtual control of the most vital and individualistic factor in modern society, the university spirit. It is to be hoped that before the federal government actually embarks on such a comprehensive and irreversible program a truce should be called of at least ten years, during which the exceedingly complex ramifications of the scheme can be analyzed by competent experts. One need not subsidize genius and one may not buy the cardinal virtues in the market place. What American medicine needs most is to be

let alone, to continue the remarkable progress of the past half century which has made medical service and research in this country equal or superior to that in any other nation, to conserve its material resources which have been poured out lavishly and intelligently by public spirited citizens, and to solve its problems methodically according to the judgment and decisions of its tried and trusted leaders. There are, throughout this country, a great number of highly competent physicians and long established medical organizations which are intimately familiar with medical problems and are dealing with them by methods tested by experience, with notable success and as rapidly as may be. Why should we transfer these multitudinous and highly technical responsibilities to a new group of relatively inexperienced persons who are far removed from the scene of action?

NEED OF EDUCATING THE PUBLIC

To forestall precipitate action by runaway political forces it will become necessary for the medical profession to undertake a systematic program of public education, pointing out the high standard of medical service in this country, the diversion of large masses of people from private hospitals to public institutions owing to artificial economic dislocations, the growing abuse of public hospitals by tired folk and malingerers, the demoralizing influence of free medical care, the necessity of personal responsibility for personal hygiene and the avoidance of disease, the ignorance of the public in seeking medical advice, and the utter futility by any conceivable program of relieving the symptoms of innumerable minor ailments or preventing death from major lethal diseases and, above all, the vast difference between useful and noxious therapeutics. For these are days when every one seems to have his own pet ideas about major problems, and the expert must prove that he is an expert by repeated argument and demonstration. A hundred years ago, Albany doctors by public demonstration convinced the public that organized medicine can still be trusted to direct progress in its own field.

UNRESTRAINED BIOLOGIC FORCES

Finally, political and economic movements now gathering momentum in many parts of the world promise to place on medicine of the future grave problems which it alone seems capable of meeting. The greatly increased tenure of life, the elimination of decimating epidemics, the enormous overproduction of foodstuffs and unrestrained reproductive fertility have made it possible for many more people to live on the earth, and in certain regions these biologic forces have brought about extreme overcrowding of the population. In some countries with national ambitions, these

factors have been exaggerated by bonuses for large families and penalties for celibacy, so that the effect of natural biologic influences have been deliberately intensified by human ingenuity. The result has been that these nations must either burst their boundaries or limit their excess population. They have chosen the former course and have frankly adopted the doctrine that henceforth biologic forces unrestrained by human intelligence shall rule the fate of nations. The inevitable result is war. The stronger must destroy the weaker. Among the lower animals nature has provided a convenient mechanism by which the stronger species devour the weaker, or natural limitations of life or deficiency of food or slight climatic changes often erase overpopulous species. No such limiting agencies apply to the human species. We have the advantage of highly developed intelligence and a rather effective control of our physical environment. The problem of overpopulation, undernourishment and unemployment is worldwide and increasing, and it is a biologic problem not to be met by peace conferences, truces, doles, public works and taxes. Neither can it be met by praying for peace or by denouncing the nations that go to war under existing conditions. It can be met only by accepting the biologic doctrine but directing it through enlightened intelligence. The human race need not submit to the natural forces that breed and destroy the lower animals. In America we have flattered ourselves that we are not suffering from these same conditions, that we are not forcing overpopulation and have not adopted the simple biologic doctrine, but is it not clear that during the recent period of expansion many more people came into existence in this country than can be comfortably supported and that jobs for everybody cannot be artificially created? In our approach to the totalitarian state are we also not attempting to solve a biologic problem by economic measures?

REMEDIAL MEASURES

Medicine is the instrument through which remedial measures conceived in the light of biologic principles can be made effective in relieving the present dilemma of the overpopulated nations. The medicine of the future will surely be called on to use all its resources to meet this problem, if it is to be solved at all. Rather than call a peace congress, a conference of biologists, physicians, churchmen and social economists should be assembled to find ways and means. Already many voices have urged the pressing necessity of establishing safe methods of birth control. Modern eugenics offers the possibility of a vast improvement in the quality of the race, for today a large proportion of living persons are unfit physically and mentally, as a result of hereditary and environmental factors. Since the problem is of national

scope, the federal government could aid in formulating public opinion by establishing a bureau devoted to the express object of improving the quality of the North American race. I venture to think that this task is a more essential function of government than are excursions into the field of curative medicine. The chief responsibility and opportunity probably lie with the university medical schools. As practical steps toward this end the medical schools of the future must stress preventive medicine, the science of nutrition, genetics, practical eugenics, antepartum service, endocrinology and all those

branches of science which tend to place us in command of those irresistible biologic forces which determine the quality of mankind. They must cordially accept the biologic doctrine but realize that biologic forces may be modified and controlled in accordance with the dictates of the enlightened conscience. Cooperation with other departments of the university will be required to prepare public opinion to accept the conclusions and adopt the program suggested by medicine, and in this field sociology, economics and philosophy will find new opportunities and incentive.

Medical College News

Medical schools, hospitals and individuals will confer a favor by sending to these headquarters original contributions, reviews and news items to be considered for publication in the Student Section.

Harvard Students After Fifteen Years

The class of 1925 of Harvard Medical School will hold a reunion in New York City, June 11, during the time of the annual meeting of the American Medical Association. Anticipating this event, Dr. William N. Wishard obtained interesting information from 100 of the 117 living members of the class. Five of the remainder live in foreign countries. The addresses of two are unknown. This class spent, on an average, three years in hospital training before assuming the actual practice of medicine; thirty-five members of the class had four years or more of training in a hospital, eighteen had five years or more and eight members had six years or more. Now at least eighty-eight members are on one or more hospital staffs. Thirty-six members answered the question about their own publications, and they had to their credit an average of 11.3 papers, monographs or books per member. Ninety-three belonged to the local and state societies and American Medical Association, three have been president of their local or state medical societies, fifty-eight are diplomates of the National Board of Medical Examiners, five are in the service of the United States. The members belong on the average to 2.8 scientific societies; two of them belong to ten and one actually to fourteen scientific organizations. Their ability to pay so many dues is explained by the fact that the average income of the members of the class was \$7,000 with a maximum of \$20,000 and a minimum of \$3,000. One member has been appointed ambassador to an important country which is much in the limelight during these troublous days. Five members are unmarried, and fifteen of the ninety-five married members have no children. One hundred and eighty-one children have followed the eighty marriages, an average of 2.6 per couple; forty-three of them have two children, eighteen have three, six have four, and one has five children. None of the class have left the profession, one has become a full professor, nine associate or assistant professors, thirty-five instructors, and one is a hospital superintendent. Thirty-five of the hundred have gone into surgery, twenty-one into internal medicine, fifteen into general practice, nine into obstetrics and gynecology, seven into pediatrics, two are secretaries of state boards of health, and two each have gone into ophthalmology and orthopedics. Forty-five of the hundred members returned to practice in the communities from which they came to medical school.

Scholarships Announced by Michigan Galens

The Galens, an honorary medical society, has contributed a scholarship fund of \$2,000 to be awarded annually to students in the University of Michigan Medical School, at Ann Arbor, the money to come from the Galens news stand in the University Hospital. The total sum will be used to form individual scholarships, not one of which is to exceed \$400. The number and size of the scholarships will be determined by the scholarship committee of the medical school, which will award the grants on the basis of the following qualifications: Recipients must be native-born citizens of the United States, must be juniors or seniors in good standing, must have completed two full years of work in the local medical school and must be enrolled at the time the grant is made. Preference will be given to students whose scholastic work in the opinion of the committee will be improved by financial aid.

Tulane's History of Medicine Society

Thirty-five students at the Tulane University of Louisiana School of Medicine, New Orleans, have been named members in the History of Medicine Society, an honorary organization founded at Tulane in 1933, the purpose of which is to foster scholarship and interest in the history of medicine and to maintain the finer traditions of the humanities in medicine. The officers elected for the coming year are Rudolph Matas Landry '42, president; Lee Roy Murphree '42, vice president; Charles M. Wilson Jr. '42, corresponding secretary; Julian Wiener '42, recording secretary; Walter Jacques Trautman Jr. '43, treasurer, and Dr. B. Bernard Weinstein, faculty adviser.

Georgia Faculty-Student Get-Together

The dean of the University of Georgia School of Medicine, Augusta, Dr. G. Lombard Kelly, proclaimed May 11-18 as Faculty-Student Get-Together Week. An auld lang syne dance was held Saturday evening in the former college auditorium, which faculty members and their wives attended. The regular meeting of the Faculty-Student Council was held Monday evening at the home of Dr. Peter B. Wright. Exercises were held Friday evening in the Dugas Auditorium, following which refreshments were served in the Physiology and Pharmacology Laboratory. The Faculty-Student Council was promulgated during the present year for round table discussions of faculty-student problems. Five members of the faculty were selected by the stu-

dent body to serve with nine students, two selected by each class, and the president of the student body. —The University System of Georgia Council, consisting of the heads, deans and many teachers in the different parts of the system to the number of more than 100, was the guest of the school of medicine April 26-28.

A students' activities fee of \$5, collected for the first time this year, has paid all students' hospital bills to date and has paid for two table tennis sets, two pool tables, and one badminton court and equipment.

Annual Lecture at Louisville

The annual Alpha Omega Alpha lecture at the University of Louisville School of Medicine, Louisville, Ky., was held at the Louisville City Hospital, April 19. Dr. John A. Bigler, assistant professor of pediatrics, Northwestern University Medical School, Chicago, spoke on "The Blood Titer of Diphtheria and Tetanus Antitoxin." Sixty-six guests attended the banquet. Dr. Lee Palmer was toastmaster. The speakers were Dr. Bigler and the two graduate members-elect, Drs. Emmet F. Horine and James H. Pritchett.

Seniors Give Notes for \$200 Each

The senior class of the George Washington University School of Medicine, Washington, D. C., has unanimously presented the school of medicine with a \$10,000 endowment fund, each student in the class having signed a noninterest bearing note for \$200.

Vitamin Patents to Provide Chemistry Fellowships

Lee I. Smith, Ph.D., head of the division of organic chemistry, University of Minnesota, Minneapolis, has donated to the university his 25 per cent share in the proceeds from manufacture and sale of vitamin E products under patents applied for as a result of his research, and the university has accepted the gift. It was specified that if and when the income is sufficient from the patents four \$750 fellowships in chemistry be established to be awarded annually to superior students. If more than that amount of money accrues the remainder shall go to establish the Lee Irvin Smith Fund, the income of which shall be used to pay the fellowships when the patents expire.

An Opportunity to Sing in New York

The Doctor's Choral Society, New York City, is open to medical and dental students who have vocal talent and desire to sing and who will promise steady attendance. Rehearsals are held at the studio of Maestro Alberti at the Hotel Ansonia, Broadway and Seventy-Third Street, Wednesday evenings.

Prizes Awarded to Interns

Dr. William J. Kerr, professor of medicine, University of California Medical School, San Francisco, announced April 6 the award of the Woodward Prizes in internal medicine. Frederick S. Howard, San Jose, now an intern at the University of California Hospital, won the first prize of \$150 for his paper on "Snake Venoms in Therapy—A Review of the Literature"; Melvin Friedman, Los Angeles, now an intern at the San Francisco Hospital, won the second prize for his paper on "Early Diagnosis of Gastric Neoplasms," and Arseny K. Hrenoff, San Francisco, won the third prize for his study of epidemic influenza of 1918-1919 in San Francisco. Sidney Rosin of Los Angeles and Emile J. Gough Jr. of San Francisco were given honorable mention.

National Board Questions in Medicine

Following are the questions used by the National Board of Medical Examiners in medicine in part II of the examination held February 12-14: (Part II of the examination is given immediately after graduation from medical school.)

Answer questions 1 and 2 and three of the remaining four:

1. Discuss the principles of the diagnosis and treatment of acute poliomyelitis.
2. What pathologic conditions in the chest may produce symptoms in the abdomen? Indicate briefly differential diagnosis.
3. What disorders of the clotting and bleeding mechanisms may occur in hemophilia, scurvy, jaundice and essential thrombocytopenic purpura?
4. What disturbances in metabolism (exclusive of basal metabolic rate) may be expected in thyrotoxicosis?
5. Enumerate the diagnostic features of the history, physical examination and laboratory data that are necessary to treat adequately a case of lobar pneumonia.
6. Discuss the diagnosis and treatment of Addison's disease.

Duke University

Dr. Halbert L. Dunn, of the U. S. Census Bureau, Washington, D. C., lectured on vital statistics before the students of Duke University School of Medicine, Durham, N. C., March 13; on the previous day, Dr. Mark V. Ziegler, U. S. Public Health Service, lectured on "Opportunities in the United States Public Health Service." "Problems of a Young Doctor in Private Practice" was the subject of an informal discussion in the Duke Hospital amphitheater, February 26, sponsored by the Nu Sigma Nu fraternity, in which questions of ethics and of the legal, social and business aspects of medical practice were discussed by Dr. Wingate M. Johnson, editor of the *North Carolina Medical Journal*; Douglas B. Maggs, of the Duke University Law School, Harold D. Meyer, sociologist of the University of North Carolina; Leroy Lewis, instructor in public speaking at Duke University, and Dr. Wilburt C. Davison, dean of Duke University School of Medicine.

Loan Funds at the University of Pennsylvania

Information about loan funds and noncompetitive scholarships available at the University of Pennsylvania School of Medicine may be had by writing to the director of scholarships and student finances, University of Pennsylvania, Philadelphia.

Among the prizes to be awarded in June 1940 at the medical school is the Dr. Spencer Morris Prize, comprising the annual income from the investment of \$28,000. The award is made to the senior medical student who shall pass the best examination for the degree of Doctor of Medicine. Among the other prizes is the Alumni Medal and a prize of \$50 awarded to the member of the graduating class who attains the highest general average in examinations.

Undergraduate Medical Association

The Undergraduate Medical Association of the University of Pennsylvania held its thirty-second annual meeting April 18. Students who have not yet received their M.D. degrees presented eleven papers. Addresses were given by Dr. James B. Collip, McGill University Faculty of Medicine, Montreal, on "Pituitary Hormones in the Light of Recent Experimental Studies," by E. A. Singer Jr., Ph.D., on "Beyond Mechanism and Vitalism" and by Dr. Samuel C. Harvey on "The Scientific Method in Clinical Surgery." Dr. Edward S. Thorpe Jr. presented the prizes. The Mary Ellis Bell Prize was won by student Renato A. Ricca '40, the John G. Clarke Prize by student Seymour S. Kety '40, and the Grahke

Simpson Priestly Prize by student Martin G. Netsky '43. Honorable mention was given to student William H. Crosby Jr. '40.

Loan Funds at Wisconsin

The income on \$5,000 bequeathed to the University of Wisconsin by Mrs. Cora R. Evans is available as a loan fund to students in the medical school. Interest is charged at the rate of 5 per cent. Loans are made on recommendations of the dean of the medical school. There is an annual prize of \$25 established by the local chapter of Phi Delta Epsilon fraternity, which is awarded at the beginning of the second year to the student who is judged to have done the best work in gross anatomy in the previous year. The university also has a number of fellowships and scholarships available under certain conditions, about which information can be obtained from the dean of the University of Wisconsin Medical School, Madison.

Alumni-Senior Picnic

At the annual picnic of the senior class of the College of Medical Evangelists, Los Angeles, May 12, Dr. Newton Evans was the faculty guest of honor in recognition of his years of effort to raise the standard of scientific training in the school. The Woman's Auxiliary prepared the picnic dinner; there was a ball game and other entertainment. Prizes were offered. The chairman of the entertainment committee was Dr. Theodore S. Kimball.

Prize at the University of Kansas

The A. Morris Ginsberg Prize of \$100 is given annually to the junior student at the University of Kansas School of Medicine, Kansas City, who shows the highest proficiency in the medical courses of the third year.

Michigan Premedical Students Organize

A group of premedical students at the University of Michigan, Ann Arbor, organized the University Premedical Society, March 27, electing Vahan A. Kalajan, a junior from Brooklyn, president of the group; John R. C. Adams, Ann Arbor, vice president, and L. J. Fink, Detroit, secretary.

The Judd Lecture at Minnesota

The seventh annual E. Starr Judd lecture at the University of Minnesota, Minneapolis, was given, March 14, by Dr. Edward D. Churchill, John Homans professor of surgery at Harvard Medical School, Boston, on "Surgery of the Lungs."

Fellowships Available at Yale

Following are some of the fellowships available at Yale University School of Medicine, New Haven, Conn.:

The William Harvey Cushing Memorial Fellowship, for research in surgery.

The Charles Linnaeus Ives Fellowship, for research in pathology.

The Knight Memorial Fellowship, for research in nervous and mental diseases.

Student Health

The Student Health Service at Long Island College of Medicine, Brooklyn, is sponsoring a series of talks on health problems to the students, the first of which was delivered by Dr. Arthur W. Grace, professor of dermatology, on "Athlete's Foot and Acne," and the second by Dr. Alfred P. Ingegno of the Student Health Service, who addressed the junior class on "Tuberculosis Among Medical Students."

Honorary Biological Society

Dr. Francis E. LeJeune, professor of otolaryngology, Tulane University of Louisiana School of Medicine, New Orleans, addressed the Lampyrids, honorary biologic society, recently in the Newcomb administration building on "The 'Significance of Hoarseness,'" illustrated with moving pictures. Sixteen new members have been elected to the Lampyrids from the advanced courses in biology at Newcomb.

Boston Chapter of Student Association

The Boston University chapter of the Association of Medical Students was recently addressed by Dr. William Barry Wood Jr., Baltimore, on "The Treatment of Pneumococcic Pneumonia." Every Friday noon the Visual Education Committee of this chapter presents medical films with comments by physicians from nearby hospitals; on March 8 the film was entitled "Lumbar Sympathectomy"; on March 15, "Cesarean Section," and on March 22, "Modern Surgical Treatment of Varicose Veins."

Michigan Internship Appointments

The majority of the members of the senior class of the University of Michigan Medical School, Ann Arbor, have made final arrangements for their internships. Twenty-two members will intern in the University Hospital in Ann Arbor, thirty-two in Detroit, seven each in Grand Rapids and Eloise, and thirteen elsewhere in Michigan, eight each in New York and Ohio, five in Illinois, three in Pennsylvania, two each in California, Texas, Wisconsin and the U. S. Public Health Service, and one in the U. S. Army.

Dr. Bailey Lectures to Illinois Students

The Illinois chapter of the Association of Medical Students sponsored a lecture at the University of Illinois College of Medicine, Chicago, February 14, by Dr. Percival Bailey, recently appointed professor of neurology and neurologic surgery. His subject was "The Development of Neurology." Dr. Bailey comes to Illinois from the University of Chicago, where he had been professor of neurology since 1928, previous to which time he had worked with Dr. Harvey Cushing in Boston.

Prize Available at Louisville

The Henry Enos Tuley Memorial Prize is available to the undergraduate at the University of Louisville School of Medicine who submits the best essay on "The Ideals of Medicine." The prize consists of the income from \$1,050 subscribed by friends of the late Dean Tuley and is awarded annually at commencement.

Society to Interest Students in Research

The Research Society of the Long Island College of Medicine, Brooklyn, held its final meeting for the year on April 10. The society serves as a medium for the presentation of original investigations by members of the teaching staff of the college and to interest the students in research. This meeting was addressed by Dr. William S. Tillett of the Department of Medicine, New York University College of Medicine, on "Special Immunological Phenomena Occurring During the Acute Phase of Infections."

Until September

The Student Section will not be published during June, July and August.

ADIPOSE TISSUE, A NEGLECTED SUBJECT

H. GIDEON WELLS, M.D.

CHICAGO

This article is to be published in two parts; the second half will appear next week.

Although adipose tissue constitutes a large part of the total bulk of many of us (18 per cent by weight of a person of average nutrition, Voit) and is subject to many physiologic variations and pathologic alterations, nevertheless it has been the subject of relatively little study. In the leading text and reference books of pathology there is scarcely a mention of the adipose tissue as being possibly an actively functioning organ and a system subject to its own diseases. Because of this lack of consideration, adipose tissue presents many unsolved problems as well as many interesting phenomena, some of which will be reviewed in this presentation.

Nearly thirty years ago the Chicago Pathological Society was privileged to have as a guest speaker that great pathologist and teacher of pathologists Prof. Hans Chiari,¹ of Prague, who spoke to us on "Die Selbstständigkeit des Fettgewebes vom pathologisch-anatomischen Standpunkte." This cast a new light on the subject for me, and the interest aroused by his lecture has kept me thinking about the topic and appreciative of the unexplored possibilities.

The most fundamental problem, the origin and nature of adipose tissue, is still not entirely agreed on. From time to time for many years anatomists, embryologists and pathologists have been discovering and rediscovering the fact that fatty adipose tissue is not merely a common connective tissue loaded with stored simple fats but, to a large extent, structurally, developmentally and functionally an independent special tissue more after the order of the true ductless glands. Nevertheless, this view of the nature of fat tissue does not seem to become widespread, as witness the rediscoveries and the enthusiasm with which they are attended. Possibly the persistence of the older idea lies in the historical fact that this was the teaching of Virchow in his "Cellular Pathology," and hence entered into the basic principles of modern medicine. This teaching was unchallenged from 1853 until 1870, when Toldt first stated that the fatty tissue of mammals is a specific organ, entirely distinct from the connective tissues.

The early view, first thoroughly presented by Flemming in 1870, was that adipose tissue is merely ordinary

connective tissue in which fat has been deposited.² This seems to be the view still generally held by those who have given no particular consideration to the subject, and it involves the assumption that any and all connective tissue can and does serve as a repository for fat when this accumulates in excess. A little reflection shows the impossibility of this conception, for it is found that fat does not become generally and diffusely deposited in the connective tissues throughout the body, even in obesity. Imagine the tragedies if the eyelids of the obese laid on the same amount of subcutaneous fat as the abdominal wall, or if the cerebral membranes became as thick as the omentum. The hands, the feet, the ears and the nose are seen to undergo much less thickening in obesity than the abdominal wall, thighs, buttocks and shoulders. An interesting demonstration of this individuality of fat tissues is furnished by Strandberg.³ A girl aged 12 years lost the skin from the dorsum of one hand through a burn. It was replaced by a graft from the abdominal wall, in making which the surgeon apparently used both skin and subcutaneous tissue. The result was satisfactory for a time, but as the girl matured and acquired the rotundity of a matron the transplanted skin failed to realize its altered status and laid on the same amount of fat as the original abdominal wall. The result was a grotesque, boxing glove effect, as shown in Strandberg's illustration.

This case also serves to demonstrate that the amount of fat deposited is not dependent on either the original innervation or the blood supply but is a specific property of certain tissues not present, at least to the same degree, in other tissues. There is reason, therefore, to believe that adipose tissue is a specialized tissue and not merely ordinary connective tissue in which fat is deposited when in excess.

Histologic and embryologic evidence has also been presented in support of this idea that fat tissue is a specific tissue, in fact a definite organ. Toldt especially advanced this view in 1870-1888, maintaining that adipose tissue is derived from special primitive fat organs, characterized by the formation of highly vascular lobular structures in which a special type of cell exists, with the function of storing and giving up fat in accordance with the supply and demand. The existence of such specialized tissue for the deposition of fat is especially well seen in certain organs and in certain species, especially the hibernating animals. Here in definite parts of the body there develop in embryonic life well defined masses of tissue, characterized by a lobular arrangement with rich blood supply in close relation to masses of cells which are rich in cytoplasm and are of polyhedral form. When such cells take on fat it is first deposited in fine granules, much as in fatty degeneration or as in the lipid-rich cells of the adrenal

cortex. As the granules become larger the cell takes on a moruloid or "mulberry" appearance. Only with the most extreme deposition of fat do all the droplets fuse into one or a few large fat spaces, and often the nucleus retains its central location and does not take the flattened form at the cell periphery characteristic of the ordinary adipose tissue. In different species the cells exhibit varying degrees of structural change during deposition of fat. Thus in rats, in mice and in hibernating fat glands the adipose cells commonly exhibit the mulberry appearance throughout life, no matter how fat the animal becomes. In adult man this appearance is completely lost in even the perirenal fat when the individual is moderately well nourished.

The existence of such specialized fat organs is well established, and the main question is whether all fat tissue represents similar specialized elements in less well defined lobules or organs or whether ordinary con-

Fig. 1.—Subcutaneous adipose tissue ($\times 225$) in extreme emaciation, showing its lobulated glandlike character and the difference from the connective tissue elements between the fat lobules. From a 5½ months infant emaciated because of inability to assimilate fat, owing to congenital occlusion of pancreatic duct. Xerophthalmia was present. (From the Children's Memorial Hospital.)

nective tissue may not undergo a transformation into adipose tissue at times or even serve as a reservoir for fat without any transformation or specialization.

Early students of the embryologic development of adipose tissue, as Kölliker or Bell,⁴ held that the earliest adipose tissue is derived from primitive connective tissue elements. They said that some cells exhibit the capacity to lay on fat while still appearing as ordinary branching connective tissue cells, while others form the so-called primitive fat organs by a transformation of the connective tissue cells into rounded or polygonal cells with abundant cytoplasm, which cells are collected in lobular groupings before beginning to take on fat. Hammar⁵ especially developed this conception of two types of fat tissue coming from the same primitive con-

nective tissue elements. He found that some of the fat tissue is formed in well defined structures, essentially fat organs, but that some of it is formed from similar cells which have not been set aside in special fat organs. In man, the perirenal fat deposits offer the closest resemblance to primitive fat organs or to the fat glands of hibernating animals. Hammar held that human subcutaneous fat was formed without preformed lobules. In some animals, such as the rat, some of the fat tissue retains the primitive glandular structure throughout life, and as it tends to become pigmented this has been known as brown adipose tissue. Hammar also thought that transition forms between the two classes of adipose tissue might exist.

Despite Hammar's statement that human subcutaneous fat is formed without preformed lobules, at times it exhibits macroscopically a lobular structure. This I have noted especially in endocrine adiposity, as after castration, and in hypophysial dystrophies. Furthermore, lobulated lipomas arise in the subcutaneous tissue, and hernias of lobules of fat are often seen. In emaciated infants also the subcutaneous adipose tissue may appear in the form of pinkish lobules, composed of large cells, rich in cytoplasm and resembling closely a glandular structure with no resemblance to ordinary adipose tissue but corresponding to the preadipose tissue described by the embryologists, or the brown adipose tissue and hibernating glands in the exhausted stage (fig. 1). Indeed, I have had specimens of such tissue sent me for diagnosis by puzzled microscopists.

Such glandlike masses of preadipose tissue in young infants have a reddish appearance when dissected out and look quite different from ordinary fat tissue with "signet ring" structure. They commonly revert after birth to the "mulberry" type of cell with fine fat globules and much cytoplasm, later again assuming the adult type.

Some authors, like Hammar, Chiari and Inglis,⁶ take the compromise position that there are two sorts of adipose tissue, both derived fundamentally from the primitive connective tissue. In one the differentiation becomes so well established that the true, permanent fat tissue is formed, with cells originally rich in cytoplasm collected in definite lobules and in glandlike relation to blood vessels. This is a specialized tissue, located in definite regions and not reverting to ordinary fibrillar connective tissue when the fat is depleted, the fat-poor cells then exhibiting their original cytoplasm-rich or "mulberry" characteristics.

The other sort of adipose tissue, according to this view, merely represents ordinary connective tissue which has, without embryonic differentiation, taken on large amounts of intracellular fat as an adventitious property because of either local or general conditions, often only temporarily. On loss of the fat such tissue reverts to its ordinary character of fibrillar connective tissue. Chiari considers the fat of the bone marrow to be of this character. Such a compromise view is convenient, but it fails to agree with the fact that in some parts of the body the connective tissues are never seen to take on the character of adipose tissue, no matter how great the degree of general adiposity may be.

That the adipose tissue is at least in part originally derived from primitive connective tissue elements is supported not only by embryologic studies, especially those of Bell, but also by its behavior in tumors derived from adipose tissue. Here, as Jacobson⁷ particularly

7. Jacobson, V. C.: *J. Cancer Research* 6: 109 (April) 1921.

points out, mucin forms in abundance, so that malignant tumors from such a source are often described as lipomyxosarcomas, or some such name. The cells that contain the fat in such tumors have been shown by Jacobson to contain mucin as well. But still it would seem that in some parts of the body fibroblasts which do not differentiate into adipose tissue early in development do not later exhibit any ability to accumulate fat or to develop into adipose tissue. Certainly the formation of adipose tissue is not a universal property of fibroblasts, since there exist areas of fibrous tissue that never exhibit the formation of adipose tissue. Mallory goes so far as to say that the fat cell is a perfectly definite type of cell formed by differentiation from a mesenchymal cell, that it is not a fibroblast, that it does not arise from one and that in emaciation it does not revert into one. He says that in emaciated infants, especially soon after birth, the fat cells often increase considerably in size, although containing no fat, and may so resemble large epithelial cells as to be mistaken for some form of tumor. This statement corresponds exactly with my own observation and experience. Even in advanced life the typical perirenal fat cells may revert in emaciation to quite the same type of lobulated, fat-free organ as in emaciated infants (fig. 2).

Maximow's⁸ extensive study of cell origins and transformations also led him to doubt the relation of fat cells to fibroblasts. He depicted the specialized fat cells in the emaciated omentum as entirely distinct from the fibroblasts and also showed fat cells developing from undifferentiated mesenchymal cells about the blood vessels. Possibly fat tissue may develop in adults from persisting undifferentiated mesenchymal cells. The fact that fat cells do not have the power to multiply may be looked on as an evidence of their high degree of specialization.

In recent years the study of adipose tissue has been particularly advanced by the work of Friedrich Wassermann⁹ and his associates, which has shown more clearly the relation of the primitive fat organ to the small vessels and its origin from perivascular mesenchymal cells related to the reticulum. Hence the fat organs are formed from the same embryonic elements as the lymph nodes, namely, capillaries and reticulum cells of the vascular adventitia, which relationship is attested by the tendency for lymphoid tissues sometimes to replace fat tissue, and conversely, as seen especially in the thymus. So too the close relationship of bone marrow and adipose tissue is explainable, and also the occurrence of extramedullary hemopoiesis in adipose tissue.

FUNCTIONAL ACTIVITY OF ADIPOSE TISSUE

In other words, the adipose tissue is to be looked on as part of the reticulo-endothelial system, a conception which suggests more active function for adipose tissue than has been generally recognized, and in harmony with the glandlike histologic character of the unfatted fat organs. For example, Bernard Portis¹⁰ showed that the ability of the omentum to produce antibodies is correlated with the occurrence in this adipose organ of aggregates of reticulo-endothelial cells which appear histologically quite like the primitive adipose tissues before fat storage has begun. Wassermann says also

that in adipose tissue "under certain conditions the blood cell formation may be reestablished, with or after discharge of the stored fatty material, the reticulum being restored in its original condition. Such lability and preparedness for functional change is characteristic in high degree of the fat organs of the omentum."

I am furthermore prepared to accept the view that even while still distended with fat the fat cells may be carrying on important functions not as yet disclosed, for the mere presence of a load of fat need not seriously impair other activities. In such distended cells there is presumably just as much nuclear material and cytoplasm as there was before the fat was deposited, and these functioning elements, being outside the fat, are in immediate contact with the blood supply over a much greater area than in the fat-free cells. Even extreme fatty degeneration and infiltration of parenchymatous cells are not necessarily associated with marked inter-

Fig. 2.—Periadrenal adipose tissue ($\times 310$) completely depleted of fat from extreme emaciation taken from a woman aged 66 weighing only 68 pounds (31 Kg.). Death resulted from cancer of the pancreas.

ference with function. The liver heavily infiltrated with fat may respond well to functional tests. Indeed, even toxic fatty metamorphosis may fail to be associated with marked impairment of function. I once carried out an experiment designed to give a crucial test to this question, using as my criterion the ability of dog liver to oxidize uric acid.¹¹ This function was selected for the test on the principle that functions acquired most recently in evolution are usually the ones most easily lost or inhibited. Now of all the steps of purine metabolism the oxidation of uric acid is the one most recently evolved, so that only mammals, and not all of them, exhibit it. Furthermore, in species possessing this function it is not present until just about birth. Therefore, thought I, if any cell function is impaired by fatty degeneration of the cells, this oxidation of uric acid should be the one to go early. So I produced maximum degrees of fatty change in dogs' livers by poisoning the

animals with both phosphorus (which attacks most the peripheries of the liver lobules) and phenylhydrazine (which attacks the centers) and tested the ability of these extremely fatty liver cells to oxidize uric acid. They did it just as well as the normal control liver tissues.

Wassermann says that the "brown fat," lobules of which are regularly found in man although in volume far less than the reticular adipose tissue, differs in being a cellular fat organ which is formed by separation out from the primitive fat organs of free cells which lay on small droplets of fat in "mulberry" fat cells, which are the true lipoblasts. When the fat is resorbed from these cellular fat organs the resulting cellular aggregates resemble paraganglionic organs. "As the fat lobules are reticulo-endothelial organs one cannot speak of fat tissue as of a simple tissue. . . . It is incorrect to distinguish between the two older conceptions of 'fat tissue' as of connective tissue nature according to Flemming,

Fig. 3.—Serous atrophy of fat ($\times 240$). Illustrating the capacity of depleted fat cells to take up water. Vertebral marrow taken from same patient described in legend for figure 2.

or as a specific tissue according to Toldt. Neither teaching is tenable with our present understanding."

Dogliotti¹² has shown that both brown and white fat tissue cells store vital dyes, like reticulo-endothelium, which process is especially well seen in depleted fat cells. Bremer¹³ has demonstrated that even the thin cytoplasmic ring about fat-distended cells exhibits the property of taking up granules of vital stains, further indicating the existence of unrealized capacities for functional activity by fat tissue even when distended with fat.

To regulate the functional activity of the fat organs an abundant nerve supply to both the vessels and the parenchyma is present, as demonstrated by Hausberger in Wassermann's laboratory. Section of the nerve supply modifies the behavior of the fat cells in storing and yielding fat. Beznák and Hasch¹⁴ have shown that

it is the sympathetic fibers that control both deposition and mobilization of fat in adipose tissue, and Boeke¹⁵ has demonstrated sympathetic nerve fibers running to individual fat cells. Sympathetic control is also shown by the occurrence of facial hemiatrophy from irritation of sympathetic trophic fibers (Goering¹⁶).

Wassermann has advanced the idea that in such organs as the mammary gland of rodents the intertubular fat tissues seem to play a role in the function of the gland as a whole. The changes required by alternating activity and quiescence are facilitated because the vascular structure of the adipose tissue makes unnecessary a rebuilding of vascular and supporting structures. Apparently when the glandular elements assume preponderance the character of the adjacent fat organ is altered, the mesenchymatous elements being crowded out of the vascular system and assuming the character of stroma. With cessation of tubular function the components of the fat organ come to the fore. Perhaps such transitions take place in other organs, which process has been designated as adiposity ex vacuo. Wassermann says that while sometimes connective tissue cells may take up fat, especially under pathologic conditions, this is merely an exhibition of a phagocytic function. But in such cases the fat, like phagocytized pigments, is a foreign material, and its taking up a scavenger or defense reaction, very different from the deposition and resorption of fat in the fat organs. The latter activity, like the taking up of iron for erythropoiesis, is a function of the reticulo-endothelial organs and not possible for fibrocytes. During fat resorption from ordinary white fat tissue the large drops do not simply grow smaller but the fat is taken up by the cell cytoplasm and consumed therein.

Eger¹⁷ in a recent review on "the fat organs and their significance for metabolism with special consideration of the so-called brown fat," considers the brown fat to be different from white fat even though they have the same origin, for the cells do not assume the signet ring type ordinarily, although some investigators maintain that sometimes they do. He found that the interscapular brown fat of rats uses much more oxygen during *in vitro* metabolism experiments, with a respiratory quotient never over 1, and so differs from white fat not only morphologically but also functionally. He also says that Wendt injected an extract of brown fat of the hedgehog into rats and observed a 20 to 30 per cent fall in basal metabolism. Why brown fat is brown seems to be a mystery, since no pigment can be found in it. Adler-Mönnich and Tiberi¹⁸ also found a difference in the metabolism of brown and white fat, for in a sugar-free Tyrode solution more sugar appeared after incubation with the brown fat, which has a greater oxygen consumption, a lower respiratory quotient and a greater anaerobic glycolysis. Hausberger¹⁹ especially has shown the ability of interscapular fat organs to form fat from carbohydrate by way of glycogen deposited in the fat cells, which is corroborated by several other investigators cited by Adler-Mönnich and Tiberi, who emphasize the influence of nerve control on storage and metabolism. The activity of adipose tissues is also indicated by Schoenheimer's²⁰ studies with fat marked

with heavy hydrogen, which showed that most of the food fat is deposited in the adipose tissue before being used.

Wassermann found that the thin rim of cytoplasm of the distended fat cell can swell up with fluids and suggests that adipose tissue may play a role in water metabolism. This view is supported by the remarkable and deceiving water losses and retentions observed in defatting treatments of the obese, as especially emphasized by Newburgh.²¹ The capacity of depleted fat cells to take up water is sometimes seen in serous atrophy of fat, as shown in figure 3, in which, because enclosed in bone, the depleted fat cells could not shrink and became extremely hydropic.

GLANDULAR ADIPOSE TISSUE

There is no question as to the specialization of the adipose tissue in certain locations and species, especially in the so-called hibernating glands. These are prominent anatomic features, with characteristic location and appearance. Rasmussen²² says that this tissue has been found in forty-seven species (five insectivora, nine chiroptera, thirty-three rodentia) most of which hibernate, but it is also present in some animals that do not hibernate, e. g., rats, mice and rabbits. So glandlike is this tissue that Buffon said that in the marmot it resembled the mammary gland of a cow. Microscopically this specialized adipose tissue differs from ordinary fat tissue in having the fat in relatively small globules instead of in a single large droplet, with a round nucleus instead of a flattened nucleus crowded against the cell wall by the fat. That is to say, the hibernating glands retain the structure characteristic of the so-called pre-adipose tissue. This is well brought out by the two illustrations from Rasmussen of human infantile perirenal adipose tissue and the axillary brown adipose tissue of the rat respectively. No matter how fat the rodent becomes, these cells do not lose their moruloid structure to become signet ring fat cells, and when the fat is depleted by starvation they retain their gland cell character, never reverting to a fibroblast character.

The function of this tissue in hibernation is not known. It is too widespread to permit of successful extirpation experiments. Once it was looked on merely as a reservoir of fat for use during the period of fasting, but this is made improbable by the fact that it can furnish only an insignificant amount of food, at best but one twentieth to one thirtieth of the tissue weight lost in hibernation. From time to time a relation to the endocrine system has been suggested, partly because of its resemblance to the fatty involuted thymus or to the vacuolated cells of the adrenal cortex. Cramer²³ points out a supposed richness in lipoids of these adipose glands as evidence of a relation to the endocrine system. Finding that these lipoids are retained in the cells during simple starvation but disappear in animals on a vitamin deficiency even without starvation, he suggests that the moruloid cells have the function of a storehouse for vitamins and lipoids. In simple loss of fat from undernutrition the lipoids of this tissue disappear to such an extent that it may look almost like a blood clot because of its great vascularity. Of some possible significance is the fact that the adrenal, and in some species the ovary, is embedded in this sort of tissue and that the adrenal cortex and lutein cells resemble the adjacent

multilocular fat cells in their richness in lipoids. In favor of Cramer's hypothesis is the fact that this structure seems to be important for hibernating animals, as indicated by its prominence in them. As it furnishes an insignificant quantity of stored food during hibernation, it may well be that it furnishes an important quality of material.

The evidence that the content of the glandular adipose tissue is largely lipoidal has been given only by microchemical methods—Cramer not having made chemical analyses—but he calls it the "lipoid gland" or "cholesterin gland." Carlier and Evans²⁴ found in the hedgehog only a trace of lecithin as inferred from the phosphorus. Cramer's ideas have received support recently from Tonutti,²⁵ who found microchemical evidence of lipid richness in brown fat and evidence that fat-soluble vitamins are stored here. Animals deprived of vitamin A or D have brown fat cells containing no plastosomes and only a fine network staining black with osmic acid. On being fed either of these vitamins this osmophil structure disappears and plastosomes accumulate, apparently storing the vitamins.

Hoepke and Nikolaus²⁶ have recently also demonstrated the probable presence of vitamin C in the hibernating gland of the hedgehog, as well as a lipid resembling cerebrin of unknown function. They suggest that water formation from stored fat in hibernating animals may provide needed water, as it is said to do in the camel's hump. Wendt's²⁷ observation that an extract of hedgehog hibernating gland injected into rats lowers basal metabolism, blood pressure and heart rate suggests that this tissue functions by suppressing metabolism during the winter sleep, perhaps through action on the endocrine tissues.

HUMAN GLANDULAR ADIPOSE TISSUE

Although man is not a hibernating animal, glandular adipose tissue of somewhat similar structure is found in some parts of his body, particularly in the dorso-cervical and interscapular region. Hatai²⁸ pointed out the resemblance of this tissue to the hibernating glands, and it was further studied by Bonnot.²⁹ It is composed of lobulated masses of adipose tissue in which the cells are mostly of the multilocular type and is associated with lymphoid tissue, a fact explained by Wassermann's observations. Its dark color in old bodies indicates its resemblance to the so-called brown fat of rodents. Its special nature is indicated by the resemblance to pancreas of the fresh tissue when well nourished; in emaciated subjects it is red because of the vascularity. Even under normal conditions its fatty character is not suspected until it is examined microscopically (Rasmussen). The fact that these masses are particularly conspicuous in cretins (Shattock) and in them disappear with thyroid treatment supports Cramer's theory that the glandular adipose tissue is related to the endocrine system, as does the histologic resemblance to adrenal cortex.

The perirenal fat tissue in man exhibits some of the characters of glandular adipose tissue, the cells being more or less multilocular when not too well filled with fat, although in well nourished adults they appear like ordinary fat tissue. In infants the multilocular type of cells is often distinct, especially if nourishment is poor.

Shaw has described multilocular fat cells in the subpleural tissue of infants, and others have observed it about the trochanters, in the axillas and elsewhere. Inglis⁶ has reported a "lipoma glandulare" and a cystic angioma arising in the interscapular gland. Reuben and Peskin³⁰ also have reported a cystic tumor in the interscapular gland of a 4 weeks infant.

SPECIALIZED FAT TISSUES

There exist in many species, of animals masses of adipose tissue so localized or so behaving that they evidently have special purposes or so located or developed that they constitute special racial or species characteristics. Among these, particularly interesting is the so-called sucking pad or corpus adiposum buccae.

Although Bichat is commonly given credit for recognizing the fatty nature of this structure, it really was described and known long before his report in 1801. It has been most exhaustively discussed and studied by Scammon,³¹ who found it present not only in infants but in adults of all ages, there being no relation between its size and the age or condition of general nutrition. Sometimes it is absent on one side and present on the other. It occupies the fossa bounded by the masseter, buccinator, zygomatic and platysma muscles. The parotid duct passes across it. The function is supposed to be to prevent collapse of the cheeks in sucking so that they are not drawn in between the jaws. Although structurally isolated, and persisting despite emaciation, it seems not to exhibit the moruloid fat cells of the glandular adipose tissue. Chemically it is said to have fats of higher melting point than subcutaneous fat (Lehndorff), but this difference is too slight to be of importance.

Fig. 4.—Steatopygy. Hottentot-Bushman type of fat deposit in male American Negro aged about 55.

significant (Shattock). Cameron³² in 1921 was able to find fifteen cases of lipoma of this structure in the literature and reported a sixteenth lipoma weighing 36 Gm. It has also been known to herniate beneath the buccal mucosa after traumatism, forming an intra-oral tumor.³³ What was interpreted as a myxosarcoma of the sucking pad in a six months fetus was reported by Zahn.³⁴

In emaciated infants the sucking pads may become extremely prominent because they are not absorbed as is the subcutaneous fat, so that they may be mistaken for abscesses or other pathologic conditions, and bilateral inflammatory hyperplasia has been reported.³⁵

What enables the fat to persist here, despite a good vascularity, when the rest of the fat is being depleted is an unsolved problem. Lasch³⁶ found the iodine number higher in the cheek pad fat than in the abdominal fat, and it was still lower in the subcutaneous fat, this being in reverse order to their rates of disappearance in emaciation; but whether these two facts are related is not known. The sucking pad may become merely a gelatinous watery mass, but still a pad, in extreme emaciation.

Of interest is the finding by Shattock of this structure in infant chimpanzees and baboons but not in a monkey.

STEATOPYGY

Shattock³⁷ has discussed at length steatopygy and other matters related to adipose tissue. He says that the prominent buttocks of Bushmen and Hottentots are the most notable human examples of such local obesity. The black Hottentots are derived from the Bushmen, who are yellow, through crossing with Bantus. These structures were studied by Cuvier in 1815 in a Bushwoman exhibited in Paris as the "Hottentot Venus." Like the camel's hump, the buttocks become flabby during emaciation.

Hooton³⁸ says that in true steatopygy the fatty mass is traversed in all directions by connective tissue and rests on the gluteus maximus. When viewed in profile the fatty mass has a shape approximating a right triangle, the mass sloping downward and inward to meet the thigh. This characteristic shape is not encountered in the majority of fat European or Negro women, in whom the buttocks are rounded rather than pointed. Miller³⁹ notes the resemblance of the fat deposits in a woman with acromegaly to steatopygy and raises the question whether racial differences may depend on genetic endocrinologic differences. The condition is not confined to the females; at Oak Forest Infirmary there has been for years a Negro with typical steatopygy who told me that his mother and a sister presented the same condition; he has no children (fig. 4).

Steatopygous figures and carvings are found in ancient Egyptian relics, believed by Petrie to represent African captives or the product of intermarriage (e. g. the Queen of Punt, eighteenth dynasty [Somaliland] about 1500 B. C.). "Darwin cites Burton to the effect that the Somal men are said to choose their wives by ranging them in a line and by picking out her who projects farthest a *tergo*." The gluteal hump is independent of any enlargement of the thigh in the modern Hottentot-Bushman steatopygy. Some early Grecian pottery figures reproduce typical steatopygy, according to Shattock. From a study of archeologic evidence, Petrie says "There is thus a series of five regions in which the steatopygous race appears, and which lie apparently from north to south in the order of successive dates of the remains." All are closely related geographically to Africa and the Mediterranean, so their common origin in Africa seems assured.

HUMPS OF CAMEL AND ZEBU

Shattock says "These steatopygous accumulations we must view, indeed, as strictly analogous to the dorsal store of fat, say, on the back of the camel." When the

camels are starved, this "hump" hangs down. It serves as a supply on the desert, the nutritive companion to the famed water supply of this beast, and is composed of unilocular fat. The hump on the withers of the zebu differs in containing some muscle, which may serve as a store of protein since no motor function is evident for this tissue. The hump of the bison is not a store of fat but is due to the length of the spinous processes of the vertebrae.

FAT DEPOSITS IN THE TAIL

In certain small marsupials this deposition is conspicuous and may serve in estivation or hibernation. Much more striking are the fat-tailed sheep, of which there are several breeds, chiefly in the Orient and South Africa. One collected by Hunter is pictured by Shat-tock. Herodotus describes such sheep as follows: "There are also in Arabia two kinds of sheep worthy of admiration, the like of which is nowhere else to be seen. The one kind has long tails not less than three cubits in length, which, if they were allowed to trail on the ground, would be bruised and fall into sores. As it is, all the shepherds know enough of carpentry to make little trucks for their sheep's tails. The trucks are placed under the tails, each sheep having one to himself, and the tails are then tied down upon them. The other kind has a broad tail which is sometimes a cubit (18 inches) across." The Jewish Bible speaks of the sacrifice of the fat-tailed ram. To this day in South Africa the tail of the sheep is supported by a small truck on wheels even as in Arabia in the days of Herodotus. Other species of animals have also localized fat deposits. In man the perirenal fat is a special depot in that it resists absorption longer than most other deposits. Salmon and other fish exhibit adipose fins that seem to be merely fat deposits and not functioning structures.

One of the first serious efforts to study the question of whether adipose tissue has any other function than fat storage utilized the broad-tailed sheep for this purpose. Schaternikoff and his colleagues⁴⁰ removed the tail, weighing 6,765 Gm., from one of these animals and found that the respiratory quotient was higher after the operation. "The adipose tissue forms fat from . . . our investigation it may perhaps follow that the role of adipose tissue is greater than is usually assumed. It is not only a simple fat reserve but it also assumes a certain part in synthetic and cleavage reactions of the living organism. These conclusions are merely provisional." These conservative conclusions from a large scale study have been fully supported by more recent studies on the fat tissues by micromethods, as indicated previously.

PERIAORTIC FAT PADS

The masses of adipose tissue at the base of the heart of dogs⁴¹ and other animals as well as in man seem to have an existence somewhat independent of the general adipose tissue. In man they seem to increase with age, independent of the amount of body fat elsewhere. They seem to be particularly prominent in persons with coronary artery disease and fibrous myocarditis and may, through their arteries, furnish a source of collateral circulation.⁴²

(To be continued)

EXPERIENCE WITH ARTIFICIAL IMPREGNATION IN TREAT- ING STERILITY

REPORT OF THIRTY-FIVE CASES

WILLIAM H. CARY, M.D.

NEW YORK

Because of the great interest physicians have manifested in artificial impregnation as a method for treating certain cases of sterility and because of the public interest evoked by reference to this subject in the popular press, it seems appropriate to report one's experience with this procedure in a series of consecutive and unselected cases. Seventeen cases in which the husband was infertile and the wife was inseminated with a donor specimen from one to six times with eight¹ successes will be briefly abstracted, and eighteen additional problems, in which the uterus was instilled with the husband's specimen a total of thirty-seven times with four pregnancies, will be analyzed. All these patients were cared for in private practice except one in the latter group, successfully treated by my associate, Dr. McLane, in the Sterility Clinic at the New York Hospital. Numerical results may be far from impressive, partly owing to discouraging conditions, but the perplexing problems encountered in the management of these cases may prove of some interest. These cases are few in number, comprising but a small percentage of the whole sterility series, because proper indications are relatively rare; many patients have an antipathy for or are uninformed regarding semiadoption by the use of a donor specimen, and I have not assumed the responsibility of recommending this procedure in a single instance. As the processes of reproduction are better and more generally understood by the public, it seems obvious that consultations concerning semiadoption will become more frequent, and physicians should be prepared to render this service.

HISTORICAL SURVEY

While contributions concerning artificial impregnation in the human species are relatively rare and often fragmentary or restricted to a very few successful efforts, one surmises that the use of a foreign specimen has been tried by many physicians in isolated and unreported cases. There is ample evidence, however, that the injection of the husband's specimen to the uterus is too frequently employed and often without understanding of the indications, the principles of technic or the risks involved. This procedure and the indiscriminating use of glandular therapy have replaced curettage as the empirical panacea for sterility and should be as forcefully discountenanced. I am informed by Professor Himes,^{1a} who made an extensive review of anthropologic literature in studying the history of contraception, that no reference to artificial impregnation by preliterate people was noted. Credit for the first successful employment of this method is usually given to John Hunter, who, in a case of hypospadias, artificially transferred the semen to the vagina. Although this case was not

1. Since this article was written, patient 353 has been successfully impregnated for the second time by cervical insemination on the tenth day of the cycle; and the very obstinate problem 446 (entered as a failure) has terminated successfully by treatment on the tenth day of the cycle, ovulation being indicated by increased cervical secretion which coincided with the lowest basal temperature record made over a period of two months, in accordance with the technic of T. T. Zuck (The Relation of Basal Body Temperature to Fertility and Sterility in Women, *Am. J. Obst. & Gynec.* 36:998 [Dec. 1938]).

reported until 1799 by Everard Home,² it is thought to antedate the artificial fecundation of a dog which was recorded ten years earlier by Spallanzani.³ In this country Sims⁴ in 1866 is credited with the first successful experiment in this field. A sterile patient with a poorly developed and retroverted uterus, complicated by cervical stenosis, was finally impregnated after many injections of the husband's specimen. He tried the method on six other patients with poor results. Three years later Girault⁵ reported a few successful results (the first having occurred in 1838), the husband's specimen evidently having been used in these cases. In the latter part of the century Gérard discussed sterility and the indications and technic for artificial impregnation in a humorously illustrated semiscientific book which is not dated and is said to be very rare. In the early part of this century several articles describing the results of mechanical fecundation in the breeding of animals made their appearance. Iwanoff's⁶ work in 1907 seems to be of major significance, and subsequent studies⁷ by French and Russian investigators are largely based on his procedures and will not be further discussed. The largest series in the human species is that reported by Schorohowa⁸ in 1927, consisting of eighty-eight cases with thirty-three successful results. Séguy⁹ reported on two series in 1935. In the first (1924-1925) a total of twenty-four treatments was given to a few women without a single successful result. A second series covering a period of five years (1924-1929) included sixteen cases with seven successful results. Donor specimens were used in only two cases. Scientific data are limited. More recently one successful case has been reported by Seashore,¹⁰ and Stokes¹¹ describes his technic and claims success in a number of cases which are not classified. There are perhaps two or three other papers discussing the theory of the procedure and the results of other investigators, and Seymour¹² relates unique experiments in this field and seems to attain results not equaled by other reporters.

In choosing a donor the physician has certain obligations to discharge for the prospective parents, but he should recognize and frankly state the limitations of responsibility which he can assume. Little difficulty has been met in securing healthy young men of education, good breeding and fine family for this purpose. Chief emphasis has been placed on character. Familial and transmissible diseases were avoided. A negative Wassermann report and a history of freedom from genital infection have been considered imperative. All donors were of American ancestry but racial factors were carefully matched. The greatest difficulty has been encountered in securing donors with high indexes of fertility as well as personal qualifications, six applicants being examined in one group to secure two donors whose

seminal criteria were satisfactory. Requests for a straight Anglo-Saxon ancestry could be fulfilled, but in one or two instances when scientifically trained patients raised the question of color of eyes and other traits I promptly refused to accept any responsibility as to the operation of the mendelian law. Inquisitive patients have been told that possibly more care had been exercised in selecting donors of good ancestry than is commonly exercised by young people in choosing their marital companions and further responsibility would not be assumed. This reply is usually satisfactory.

LEGAL CONSIDERATIONS

Laws governing general medical practice are, of course, applicable to this procedure but I am informed that there is no specific statute in New York state regarding this work, and an expert in real estate law found no ruling on property rights relative to this method of semiadoption. To recommend any legal procedure would probably be unwise, as the physician will doubtless be guided by circumstances and personalities. A simple written consent signed by the husband and wife and histories filed indicating that both parties have submitted to preparatory examinations should constitute adequate protection. Instances may arise in which patients are slightly known and more formal permission may be desirable. In one instance, in which the inquiring couple were being forced by a wealthy relative to take this action against their obvious desires, I refused to proceed. Patients are told, incidentally, that no foreign body such as semen can be introduced within the uterus without a slight risk of reaction and that the same chances of abnormal labor and defects in progeny are involved as in any delivery. Patients have been influenced not to invite the chance of later trouble by selecting any member of the family as donor. Certain legal aspects of this problem and an interesting suggestion of subsequent legal adoption may be found in an editorial in *THE JOURNAL*.¹³

TECHNIC

Only principles in technic can be properly discussed, for lack of experience, inability to correlate variations in procedure with results and the unknown factors involved make definite recommendations impossible and an imposition on credulity.

While experimenters, too numerous and well known to permit naming, have given much information regarding the correlation of ovulation with the menstrual cycle, the selection of the day on which to introduce the semen remains a perplexing problem. The daily examination of vaginal smears to determine the date of ovulation is cumbersome and difficult of interpretation, and much obscurity persists as to whether the demonstration of the follicle-corpora luteum sequence of influence is a certain criterion of the liberation of a healthy ovum. With rare exceptions I have found the menstrual cycle to vary from twenty-six to thirty days in length in the so-called regularly menstruating women, and greater differences are not rare. Except in cases studied by Papanicolaou I have chosen the eleventh to the fifteenth day of the cycle for insemination, depending, when possible, on predominant habits as noted in the past menstrual calendar. Earlier days have been selected for patients with habitually short cycles.

With few exceptions, semen specimens have been produced at the office, collected in a previously prepared sterile and absolutely dry glass container and

transferred to the woman as soon as sufficiently fluid to permit easy handling in a sterile dry cannula. In one of our successful cases, however, the husband's specimen was more than an hour old. Various cannulas have been tried, but the most suitable one for general use seems to be that which I described some years ago for aspirating the cervical secretions and now widely distributed for that purpose. Arrangements are so made as to eliminate any chance of contact between the donor and the patient.

For the operation, the patient is placed in the Sims position because she is better relaxed, her vision is directed from the field of operation and the Sims speculum can be better removed without spilling the bulk of semen, which is to remain bathing the cervix whether simple insemination or injection to the uterine cavity is carried out. When injecting a donor specimen into a patient having a fully patulous cervical canal with normal secretions, a few minims of semen (0.5 cc. or less) is held in contact with these secretions for approximately five minutes to insure ample sperm invasion. Success has also followed simple insemination in such cases and may be as efficient. When the husband's specimen is to be instilled into the uterine cavity not more than 10 minims (0.6 cc.) is used so that there is no danger of invading the tubes and producing severe colic and possibly inflammatory reaction. Under proper conditions only slight pressure is usually required, but I have subjected semen to a pressure of 200 mm. of mercury for one minute without altering its microscopic appearance. When the specimen has been placed and evidences of the procedure have been removed from the room the patient assumes the dorsal position and continues reclining for at least one half hour. A very few patients have suggested and tried emotional preparation at home just prior to insemination. Physiologic results are unevaluated.

INDICATIONS FOR DONOR SPECIMEN

The infertility of the husband, established beyond reasonable doubt by the causative factor or the failure or inaccessibility of appropriate treatment, is the primary indication for utilizing extramarital semen. The consultant should, when considered necessary, confirm the validity of this indication and ascertain that the husband is assured of the facts and reconciled to the procedure. In one instance in which persistent necro-spermia was diagnosed the rarity of the condition and the history of repeated transportation of the specimens in rubber containers led to a reexamination which revealed the normal fertility of the husband. The histories to be abstracted record hopeless azoospermia as a prevailing indication, but in a small minority high degrees of seminal deficiency unimproved by competent treatment seemed ample reason for the use of a donor specimen. Two couples in this group reported marital pregnancies one and three years, respectively, after delivery; one occurred after marked seminal improvement resulting from previously declined treatment, and the other was proved to be a rare instance of fecundation by a specimen with a low sperm count (16,000,000 per cubic centimeter, postgestational). In the entire sterility series there is an 0.8 percentage of cases in which pregnancy was brought about by specimens with normal motility but greatly reduced cell counts (19,000,000 or less per cubic centimeter, postgestational count). Hotchkiss¹⁴ has reported similar cases.

14. Hotchkiss, R. S.; Brunner, H. K., and Grenley, Philip: Semen Analysis of Two Hundred Fertile Men, *Am. J. M. Sc.* 196: 362-384 (Sept.) 1938.

Further essential indications, both positive and negative, refer to the wife and include (a) an understanding of and a stated desire for this method of fecundation, (b) reasonable evidence of her fertility, and (c) the absence of factors which would greatly increase the immediate risk of the procedure or seriously complicate an ensuing pregnancy. It would be presumptuous, even if space permitted, for me to attempt a definition of female fertility. A careful history and an examination of the wife should be included in plans for the treatment. The past history should eliminate suggestive symptoms of genital infection. One should emphasize that report of menstrual deficiency is not a reliable index of infertility, but when it is associated with obvious degrees of uterine underdevelopment serious doubt must be entertained. The examiner should note patulousness of the cervical canal to the cannula when artificial spermigration is to be undertaken, and endocervicitis should be regarded as a contraindication to uterine instillation. The pelvis should be free from palpable pathologic change and the patency of the tubes demonstrated. Partial occlusion presents implications which should be weighed with reference to the effectiveness of the method and the risk of ectopic pregnancy. Finally, the wife should be free from any disease which would render child bearing a hazardous undertaking.

While case abstracts seem essential for scientific appraisal, brevity demands that normal and irrelevant items be excluded. The reader may assume that within my ability constitutional factors have been weighed, sexuality appraised, adolescent histories reviewed, hereditary and endocrine influences cautiously considered, metabolic readings obtained, tubal patency confirmed, male urologic studies carried out and anatomic and functional observations correlated in all cases. Some interesting but nonessential facts have been omitted to safeguard identification. Unless otherwise stated, sterility was primary and deliveries have been successful to date. The day of menstrual onset is counted as the first day of the cycle, and insemination was carried out but once in any monthly cycle.

REPORT OF CASES

CASE 427.—The indication was azoospermia. Married three years, the wife, 23, was of normally feminine type. Menstruation, starting at 11, had a twenty-eight to thirty-five day cycle and a five day period with dysmenorrhea. Obesity occurred at 14 (170 pounds [77 Kg.]). Amenorrhea and late periods were experienced while studying in Europe. Acute antelexion and stenosis were corrected under anesthesia. Endometrial biopsy (twenty-third day) revealed secretory and proliferative fragments. Six trials (twelfth to sixteenth day) failed. Normal ovulation was questioned. I arranged a study of vaginal smears by Papanicolaou, who reported very faint ovarian influence. Thyroid extract was begun (basal metabolic rate was -8), and two months later three postmenstrual injections of gonadotropic substance were given. Success followed cervical insemination on the fourteenth day of that cycle.

CASE 466.—Azoospermia was present. Permission and arrangements, including selection of the donor by the family, were carried out from a distance by cooperation with the family physician. The patient, 29, married five years, was uncooperative, studiously vague and chiefly interested in sight-seeing. Preliminary study was inadequate. Menstruation was normal, of twenty-eight day type. The specimen was sent by messenger without data and found of less than fair grade. Injection made at the end of the second week of the cycle under my protest gave an unknown result; failure was assumed.

CASE 211.—Semen was highly deficient. Treatment was unavailable; sterility had lasted one year. The wife was 23. Intermittent amenorrhea in adolescence was now relieved, with a normal cycle. Antelexion of moderate degree was noted.

Insemination of a donor specimen at the end of the second week of the cycle was successful.

CASE 406.—There was azoospermia. Married five years, the wife was 25, of small stature and immature type with mild uterine hypoplasia. Menstruation, starting at 14, had a twenty-eight day cycle and four day period. Donor specimens, in accordance with vaginal smear determinations by Papanicolaou, were injected on the fifteenth, tenth, thirteenth, twelfth and finally with success on the thirteenth day of the cycle. Dysproportion necessitated cesarean section.

CASE 396.—The specimen was highly deficient, with only slight improvement. Married six years, the wife, 27, had asthma during adolescence and pneumonia at 14. Menstruation, starting at 16, had a thirty day cycle and five day period. The pelvis was normal. The endometrial biopsy revealed a normal secretory phase. The average basal metabolic rate was -16 . Continuous thyroid therapy was given. A donor specimen was introduced on the fourteenth, thirteenth and fifteenth days of cycles with failure to date.

CASE 353.—Highly deficient semen with many abnormal cells was unimproved by capable treatment. Married six years, the wife, 31, had mild uterine hypoplasia and cervical stenosis. Menstruation, starting at 13, had a twenty-seven day cycle and five day period. Office dilation was done to accommodate the cannula. After two requested and unsuccessful attempts with the husband's specimen, success followed the second trial of a donor specimen on the eleventh day of the cycle (incidental study by Papanicolaou).

CASE 244.—Highly deficient semen in an otherwise healthy man was unimproved by treatment. Married fourteen years, the wife was healthy but had marked uterine hypoplasia, a long conical cervix and very scant periods. Menstruation, starting at 13, had a twenty-eight day cycle and three day period. Past history included curettage and x-ray stimulation to the ovaries. At the age of 42 a trial donor specimen was urgently requested to exhaust the possibility of relief. Two attempts on the eleventh and twelfth days of cycles failed, and adoption was advised.

CASE 446.—Azoospermia was present. Married three years, the wife, 32, was normally feminine in type, with normal pelvis and a short menstrual cycle—from twenty-three to twenty-six days, with onset at 14 and a five day period (the patient refused any study which might indicate failure of ovulation and elected repeated trials). Attempts on successive months on every day of the cycle from the seventh to the thirteenth, inclusive, have failed to date. Incidental empirical treatment favorable to ovulation was given.

CASE 340.—There had been suspension of sexual relations and sterility (secondary). The wife, 23, was married before she was 17. Gynecologic history began at 18. Abortion was induced in the Far East and the later history suggested acute salpingitis while on shipboard. The pelvis was sensitive but without palpable pathologic change. Contraindications were emphasized but the patient insisted and gave a written release from responsibility. Two trials on the twelfth and twenty-second days of cycles failed. Tubal reaction followed the second trial.

CASE 245.—Highly defective semen and subnormal masculinity were treated unsuccessfully. The wife, 28 and sterile four years, had a normal pelvis and menstruation. Insemination with a donor specimen was done on the fourteenth, the tenth, and finally, successfully, on the fifteenth day of the cycle.

CASE 447.—Azoospermia was present. Married four years, the wife, 27, was hyperfeminine and gracile in type; she had a scientific career. Menstruation, starting at 13, had a short cycle (eighteen to twenty-five days) and a seven day period with slow onset. Retroversion was correctible by pessary. The basal metabolic rate was -14 . No response followed thyroid therapy, calcium or gonadotropic substance. Secretory endometrium was noted on the fifteenth day of the cycle. A donor specimen was injected on the eleventh, tenth, ninth and eighth days of cycles without result.

CASE 449.—Azoospermia was present. Married six years, the wife was 30. Menstruation, starting at 11, had a thirty day cycle and six day period. The pelvis was normal except for

moderate antelexion and one small myoma (3 cm.). Injection of donor specimens on the twelfth, fourteenth and fifteenth days of cycles failed.

CASE 465.—Azoospermia was present. Married ten years, the wife, 34, had a normal pelvis and normal twenty-eight day cycle. Success followed insemination on the eleventh day of the cycle. There was another success two years later with subsequent miscarriage.

CASE 402.—Oligospermia and poor motility were unimproved by prolonged treatment. Married three years, the wife was 22. Menstruation, starting at 12, had a thirty day cycle and five day period. The pelvis was normal. A donor specimen was injected on the fourteenth day of the cycle, as noted by Papanicolaou, with success.

CASE 343.—Testicular atrophy followed typhoid at puberty. Married six years, the wife was 34. Menstruation, starting at 14, had a twenty-four to twenty-six day cycle and three day period. The pelvis was normal. The basal metabolic rate was -13 . Thyroid therapy was given. A donor specimen was injected twice on the eleventh and finally with success on the eighth day of the cycle.

CASE 411.—The specimen was poor, but one child was born after a three year wait. Married ten years, the wife, 30, had several years' secondary sterility. A trial donor specimen was requested by the family physician because of the wife's mental condition. The pelvis was normal except for viscid cervical secretion. Menstruation, starting at 13, had a thirty day cycle and four day period. A trial on the thirteenth day was without success. The psychologic state improved.

CASE 436.—Azoospermia was present. Married three years, the wife, 26, had a normal pelvis of male type. Menstruation, starting at 16, had a thirty day cycle and seven day period (amenorrhea occurred with change of environment). Trials on the fifteenth and thirteenth days of cycles failed.

INDICATIONS FOR HUSBAND'S SPECIMEN

The indications for injection of the husband's specimen into the uterine cavity for the relief of sterility are relatively rare. Many of the cases in our husband series were unsuitable, but the method was employed (when safe) in response to specific requests which involved ethical and psychologic considerations.

Failure of insemination or the inability of sperm cells to migrate to the cavity of the uterus because of weakness of the specimen or chemical or mechanical obstruction of the cervical canal constitutes the general indication for the procedure. As a matter of fact, however, most of these factors are correctible and such an attack on the problem is more efficient management.

I feel wholly unprepared to fix any standard criteria of semen defects which may justify or contraindicate the procedure. Postcoital studies of sperm migration may be found of value under proper conditions. Infection anywhere in the seminal tract calls for urologic care both as a curative and as a precautionary measure. The significance to be given a high percentage of abnormal cells in the husband's specimen has been found a disturbing problem. As an experimenter, Engle¹⁵ doubts the validity of the microscopic appearance of the cell as an index of its potential importance in abnormal pregnancies, while Williams¹⁶ in a private communication relates evidence in animal reproduction which tends to show a cause-effect relationship. At the present time the physician has little positive evidence to help him in making a decision. Contraindications of a gynecologic nature have been discussed.

15. Engle, Earl, associate professor of anatomy, Columbia University College of Physicians and Surgeons.

16. Williams, W. L., professor, School of Veterinarians, Cornell University.

The successful cases in this group are abstracted as they present, in principle, indications commonly encountered.

CASE OF MRS. S. (Dr. McLane).—The husband was 35. The couple had been married eight years. There were hypospadias and incompetent relations. The wife, 30, had normal menstruation until onset of menorrhagia during the last eighteen months. A large single intramural myoma and patent tubes were noted. Myomectomy was done in February 1935 with a subsequent normal iodized oil picture. Beginning four months later, the husband's specimen was introduced on the eighth, the ninth, and successfully on the fourteenth day of the cycle.

CASE 254.—Semen was subnormal but rated potentially fecundating. The husband's duties precluded treatment. The couple had been married four years. The wife, 31, starting menstruation at 14, had a twenty-eight day cycle and five day period with rare ovulatory spotting. Two years before, the referring gynecologist had operated for adherent ovaries and retroversion fixed by endometriosis. The pelvic condition was satisfactory but spermigration was subnormal. Semen was introduced on the eleventh day of the cycle with success.

CASE 360.—Semen was normal. The couple had been married six years. The wife, 28, was sturdy but sensitive. Occasional colitis was unexplained after careful study. Hypothyroidism (—18) was present. The past history included two years' intermittent glandular therapy and dilation for disabling dysmenorrhea. Menstruation, starting at 13, had a twenty-seven to twenty-nine day cycle and three day period and was scant. There was marked obstruct anteflexion. A stem pessary was placed but found uncomfortable and removed, with relapse. By manipulation of the cervix semen was injected beyond the obstruction, the twelfth day of the cycle, successfully.

CASE 405.—The husband, 32, had deficient semen, transient impotence and hypothyroidism (—24). Definite improvement occurred in a few months. The couple had been married four years. The wife, 28, had marked anteflexion with cervical stenosis obstructing study. Menstruation, starting at 10, had a twenty-eight to thirty-five day cycle and four day period. Dilation was done for dysmenorrhea and diagnosis. Sterility persisted. There was relapse of stenosis. Semen was injected, with angulation reduced, on the eleventh day of the cycle and repeated on the twelfth day, with success.

In the fourteen unsuccessful cases, only two wives presented criteria of normal fertility. The fertility of five husbands was doubtful and none of the cases, in my tentative opinion, offered ideal indications. It is neither easy nor indeed always ethical to deny arbitrarily a trial for patients who come with hopeful expectations. Five couples were content, however, with a single effort.

One patient, after two failures under unfavorable conditions, was returned to her obstetrician with recommendations for care which resulted successfully in two months. Another, from a southern republic where some form of tracheloplasty had been performed, was found after an unsuccessful trial to have a high cervical stenosis barring the finest probe. After study and appropriate attention the patient returned home and reported a normal delivery fourteen months later. Seven women had suffered from marked endocervicitis, which in five instances had been preceded by induced abortions; this was followed, in one instance, with a wish-bone contraceptive pessary. All had been treated by cauterization with fair clinical results. The other two patients, young and intelligent, acknowledged gonorrheal infection. One, after intermittent treatment by various physicians, had submitted to cervical amputation without cure of the discharge. Though the smear was negative contraindication was urged, but the patient, after interviewing her physician, elected to take the risk twice. The other patient had been under expert supervision almost continuously both here and abroad. Excellent results had followed ionization of

the cervix, but imperative operation had left but one tube (now reported patent) and a portion of one ovary on the same side. The attending gynecologist reported vaginal evidence of ovulation on the eleventh day.

Of the five additional failures, two were charged to marked seminal deficiency; in another case seminal defect was concomitant with marked uterine hypoplasia and oligomenorrhea; thickened ovarian tunicae had been noted at previous operation in another, and, finally, one patient gave suggestive signs of pelvic tuberculosis.

Clinical data and impressions have been briefly reviewed, but many of the biologic facts still belong among the imponderables.

57 West Fifty-Seventh Street.

TREATMENT OF MUSCULAR DYSTROPHIES AND ALLIED CONDITIONS

PRELIMINARY REPORT ON USE OF VITAMIN E (WHEAT GERM OIL)

SIMON STONE, M.D.

MANCHESTER, N. H.

The last decade has witnessed a renewed interest in the etiology and treatment of the muscular dystrophies and allied conditions. Milhorat, Techner and Thomas's¹ study of creatine metabolism and the results of the administration of aminoacetic acid to dystrophic patients and Meldolesi's² investigation of pancreatic function and his observation of a deficiency of proteolytic and tryptolytic enzymes in muscular dystrophies helped to focus attention on the metabolic aspects of this disorder. That vitamin E deficiency might also play a part in the causation of this condition was suggested by the observation of Blumberg³ of muscular changes, growth retardation and malnutrition in young rats on a vitamin E deficient diet and by the production of paralysis in older rats suffering from avitaminosis E by Ringsted⁴ and Burr, Brown and Moseley.⁵ The dystrophic nature of these muscular changes was pointed out by Goettsch and Pappenheimer⁶ in the guinea pig and rabbit and by Olcott⁷ in the rat.

HUMAN MUSCULAR DYSTROPHY AND VITAMIN E

The possibility that muscular dystrophy in the human being was related to the type of muscular dystrophy observed in the guinea pig and rabbit maintained on a vitamin E deficient diet suggested the investigation of the influence of the addition of vitamin E (wheat germ oil) to the regular diet of a number of patients with muscular dystrophy and muscle atrophy. The patients consisted of a group of children with dystrophies seen

From the Neurological Service of the Elliot Hospital and the Crippled Children's Services of the State of New Hampshire.

Dr. Ezra A. Jones, Medical Director of Crippled Children's Clinics of New Hampshire, and Dr. Mary M. Atchison, of the New Hampshire State Hospital, assisted in this investigation.

at the Crippled Children's Clinics of the State of New Hampshire. Most of the patients were ambulatory and three were hospitalized for observation for a short time. The group included thirteen patients with muscular dystrophies, one patient with muscular atrophy following anterior poliomyelitis and one patient with advanced muscular atrophy coming on after an attack of neuro-myeloradiculitis. In seven cases the treatment has progressed long enough for one to form definite conclusions as to the results.

METHOD OF TREATMENT AND DOSAGE

The first patient with muscular dystrophy was placed under treatment on April 21, 1939. He was given a proprietary mixture of wheat germ oil in capsule form, one capsule three times daily, each capsule containing 3 minims (0.2 cc.) of the oil, or a total of 9 minims (0.5 cc.) of wheat germ oil a day. Later it was found more expedient and less expensive to administer the oil in milk or with the food instead of in capsules, and the dosage was also increased to 10 minims (0.6 cc.) three times daily. The addition of yeast tablets to the diet and the increase in amino acid intake through daily feedings of gelatin have also brought a more rapid response for the better. At present the oil is administered in a mixture with liquid vitamin B complex, with which it forms an imperfect emulsion, simulating in taste malt and cod liver oil mixtures. Each gram of the oil is standardized to contain 2 Evans-Burr units of vitamin E, and the usual dosage is 4 cc. from three to four times daily, of one to seven parts suspension of wheat germ oil in vitamin B mixture. The patient thus receives about 2 cc. daily of wheat germ oil, together with an ample supply of the vitamin B complex.

The response to treatment is usually prompt. At first improvement in appetite is noted, then disappearance of pain on exertion, followed by greater resistance to fatigue and lastly by replacement of rubbery muscles by normal muscle tissue. Rise in growth and weight was noted in all the younger patients, and also an increase in the sense of well-being. The medication in the present form is usually well tolerated by all patients.

In cases of muscular dystrophy of long standing with contractures and deformities, the concentration of the oil in the mixture has been increased, the patient thus receiving from 4 to 6 cc. of wheat germ oil daily. No unpleasant after-effects have been reported by the patients receiving this stronger mixture.

REPORT OF CASES

The first patient had pseudohypertrophic muscular dystrophy superimposed on Fröhlich's syndrome. He received antuitrin S subcutaneously and wheat germ oil orally. The improvement in the muscular dystrophy was rather spectacular, while response to the antuitrin S was slower but very definite.

CASE 1.—A boy aged 14 years, admitted for observation to the Balch Hospital in Manchester, N. H., through the Crippled Children's Clinic, April 18, 1939, was in good health till two and one-half years before admission, when difficulty in walking developed, and he complained of excessive fatigue, especially on going upstairs. He also had difficulty in getting up from a sitting position and for the last one and one-half years had been completely bed ridden and chair ridden, entirely unable to help himself. He also developed contractures of both legs from being kept tied in a chair in the daytime. His past history was noncontributory. Delivery was normal and he was breast fed as a child. He also had all childhood diseases without

sequelae. As a young boy he tended to be rather obese. No family history of muscular dystrophy was obtained.

The patient was very obese and was unable to move any part of his body except for raising his head and slight movement of his toes. He had a cherubic facial expression, with an obese body and fat mainly distributed over the abdomen, breasts, shoulders, arms, thighs and legs. A large apron of skin and fat over the lower part of the abdomen covered an infantile penis. The testicles were very small. The fingers were tapering, with the proximal phalanges padded with fat. The cranium and cranial nerves were normal. No sensory changes were found. Deep reflexes were not elicited.

The generalized muscular weakness and the displacement of muscles by fat suggested the diagnosis of pseudohypertrophic muscular dystrophy in a patient with Fröhlich's syndrome. In the hospital, at first the patient was unable to feed himself and had to be turned over frequently as he was unable to change his own position. He was placed April 19 on antuitrin S, 200 units every other day, and thyroid extract, one-eighth grain (0.008 Gm.) twice daily. April 21 he was placed on proprietary capsules, containing 3 minims of wheat germ oil each, given three times daily. Three days later the dose was increased to 9 minims of the oil three times a day. Dried yeast tablets were also added to his diet. April 29 he was able to abduct his arms without assistance while in a lying position, some movement appeared in his fingers, and toe movements appeared normal. Both legs still appeared contracted at the knees, with the achilles tendon also contracted on the left.

On May 2 contractures of the legs appeared less marked. He was able to raise his arms and hands by climbing up on his face while in a semisitting position, was able to turn over without assistance, and the finger tips appeared less tapering because of loss of fat around the proximal phalanges. May 6 he was able to abduct his arms; the deltoid contractions were definitely palpable; the finger grip was much stronger; the contractures of the legs nearly disappeared, with the assistance of daily stretching and local massage. Fat around the abdomen also shrank down, and the patient's face appeared less full. As the family moved out of the state, he had to leave the hospital. When last heard from, he continued to gain while taking wheat germ oil and yeast tablets daily.

Case 1 is of especial interest because of the rapid return of strength after the patient began to receive the wheat germ oil. There were no ill effects from the oil and I felt that the addition of yeast tablets to the oil increased its potency.

CASE 2.—A boy aged 2½ years was first seen May 15, 1939, at the Balch Hospital in Manchester, N. H., through the New Hampshire Crippled Children's Clinics. When he first began to walk, at the age of 1 year, his mother noted that he had difficulty in getting up from a sitting position and would rise on himself. Also contractures of the tendons of the toes developed on both feet.

The family history was noncontributory on the paternal side. On the maternal side, two great-uncles were crippled and one died at the age of 14 in England from a crippling condition which probably was a muscular dystrophy. Four maternal uncles had a condition similar to that of the patient, one of them dying from it at the age of 13 and the others being considerably crippled as a result of this infirmity.

When examined, the patient appeared normal in size but definitely overweight. He walked with a waddling gait and there was some lordosis of the lumbar spine. He had considerable difficulty in going upstairs and would get up from a sitting position in a definitely dystrophic manner by rising on himself. The muscles of the shoulder girdle were weak and the gastrocnemii hypertrophied, with a rubbery feeling to them. Deep reflexes were not elicited.

He was placed on wheat germ oil 7 drops three times daily. When seen on July 18 some slight improvement was noted in his getting up from a sitting position, although he still showed considerable weakness of the shoulder girdle muscle as evidenced by his falling through when being lifted by his elbows. He was then placed on a mixture of wheat germ oil and vitamin B complex, 1 ounce of the oil to 7 ounces of vitamin B

complex, in teaspoon doses three times daily. A recheck one month later showed him able to get up without rising on himself, the muscles had lost their rubbery feeling and he could be raised from the floor without falling through. According to the mother he is able to play more and walk up and down stairs without becoming fatigued. He has continued to gain on the same medication and is nearly normal in strength at present.

The next patient is an uncle to patient 2. Two uncles and three brothers had a similar disorder. It has been transmitted through the maternal side, with no female members of the family involved.

CASE 3.—A boy aged 8 years, first examined March 28, 1939, had been having difficulty in getting up from a sitting position and had been stumbling and falling frequently on walking.

His birth was normal. He walked at 11 months. He had anterior poliomyelitis at the age of 1 year, which left the right leg atrophied and weak.

The boy walked with a markedly waddling and unsteady gait. There was advanced atrophy of the muscles of the shoulder girdle, thorax and spine and hypertrophy of the gastrocnemius and soleus on the left with a rubbery feeling to the muscles. The left leg muscles were atrophied as a result of old poliomyelitis. The muscle strength, however, was much greater in the atrophied leg, indicating that possibly the previous attack of poliomyelitis had prevented the dystrophy involving the right leg. There was marked lordosis of the lumbar spine, and both glutei were hypertrophied and replaced by fat. There was generalized absence of deep and superficial reflexes.

Treatment with aminoacetic acid and a high gelatin intake for two months produced no change in his condition. May 4 he was placed on wheat germ oil 10 drops three times daily. He received the medication for three months and a definite gain was noted in his condition, in that he was better able to get up, complained of less pain on walking and exhibited some increase in muscle power. In January 1940 he was placed on a mixture of wheat germ oil and vitamin B complex and since then there has been more increase in muscle strength and the muscles of the legs have appeared less rubbery.

Case 3 is of interest because of the moderate improvement on wheat germ oil alone and marked and more rapid improvement when a mixture of vitamin B complex and wheat germ oil was administered simultaneously. The rare coincidence of muscular dystrophy and anterior poliomyelitis was also somewhat confusing diagnostically, for the paralyzed leg appeared much stronger and entirely unaffected by the dystrophy while the other leg was of much larger circumference but with rubbery and dystrophic musculature. The response to treatment was also rapid and became apparent within a few weeks.

CASE 4.—A boy aged 14 years was seen at the Crippled Children's Clinic at the Balch Hospital on Aug. 1, 1939. For two years his mother had noted that he was losing strength in his arms and that he was unable to abduct them as well as he could previously. The scapulas would stand away from the chest wall when he tried to lift his arms.

The patient had a somewhat expressionless facies, flattening of the nasolabial folds, atrophy of the buccinators and masseters and marked hypertrophy of the upper and lower lips, which were pendulous and gave the face a grotesque appearance. There was atrophy of the trapezii, rhomboids and serrati, with the scapulas winging away from the chest wall; the latissimus dorsi and pectorals were involved. Elevation of the arms was limited to 100 degrees. On an attempt to raise the arm the entire shoulder girdle moved forward.

The patient's past history was noncontributory. The family history is of significance in that one aunt has the same type of dystrophy as the patient except for absence of lip hypertrophy, but with marked involvement of muscles of the spine and lower extremities.

The patient was placed at first on aminoacetic acid and an increased gelatin intake of 2 pounds (0.9 Kg.) a month, and

also thiamin chloride from 10 to 15 mg. at weekly intervals for six weeks, without change in his condition. On September 15 he was placed on wheat germ oil, 10 minims three times daily. A slight improvement was noted in that the muscles appeared less rubbery, but he was still unable to raise his arms satisfactorily. In December he was changed to a mixture of wheat germ oil and vitamin B complex, and since then his gain has been more rapid. The rhomboids are functioning more adequately now, and winging of the scapulas is less prominent. He is able to abduct his arms better and does not fall through when lifted by his elbows. The face is also fuller and the grotesque facial appearance less apparent. The hypertrophy of the lips, however, has remained unchanged.

The case of Landouzy-Dejerine's type of paralysis just described is of interest because of the rather uncommon association of marked hypertrophy of the lips with atrophy of muscles of the face. The patient responded well to treatment with wheat germ oil and vitamin B, while no improvement was obtained with thiamin chloride and gelatin and less change for the better with wheat germ oil given alone.

CASE 5.—A boy aged 8 years was seen for the first time Jan. 1, 1939, because of stumbling while walking, pain in the lower extremities on going upstairs, and spinal deformity. His birth was normal. His early life was uneventful except for a fall from a crib at the age of 1 year.

The patient is one of three siblings and there is no history of muscular disturbances in any other members of the family.

Physical characteristics included light soft hair and very light complexion, short fingers and spade shaped hands. The gait was unsteady and waddling. He got up from a sitting position by rising on himself and fell through when lifted by his elbows. Generalized muscular atrophy involved muscles of the shoulder girdle, the biceps and the triceps. There was greatly accentuated lumbar lordosis, with protuberant abdomen as a result of weakness of the abdominal muscles. The gluteal muscles were slightly hypertrophied, and so were the gastrocnemii, with a rubbery consistency. The feet were pronated. There was marked angioneurotic edema. No sensory changes were noted. The vibration sense and coordination were normal. Deep and superficial reflexes were present and within normal limits.

A diagnosis of pseudohypertrophic muscular dystrophy was made and the patient was placed on aminoacetic acid orally 15 Gm. daily, increased gelatin intake, thyroid one-eighth grain twice daily, and thiamin chloride 3 mg. daily. There was no improvement in his condition under this medication. In November the patient was placed on a mixture of wheat germ oil and vitamin B complex, a teaspoon three times daily. Within two weeks a definite change for the better was noted. The pain in walking disappeared and the muscles gradually began to lose their rubbery consistency. When rechecked on Jan. 17, 1940, he was able to get up without rising on himself, he could be lifted up by his elbows without falling through, and he was able to walk up and down stairs without complaining of pain. The muscles also had a normal tonus.

Case 5 is of interest because of the failure to improve under large doses of aminoacetic acid and the spectacular change for the better with vitamin E and vitamin B complex therapy.

CASE 6.—A girl aged 14 years, seen at the Manchester Crippled Children's Clinic Sept. 28, 1939, complained of difficulty in walking, weakness and inability to close the hands, wrist drop, muscular weakness and easy fatigability. She was apparently well till May 1939, when there developed a flaccid paralysis of all four extremities, which continued for about a month. She had no sensory changes and no bladder disturbances at the time. She was hospitalized for several months and received large doses of thiamin chloride intravenously. This brought some return of function, and in August she was able to be up and around. At the time of leaving the hospital she had bilateral foot drop and wrist drop, generalized advanced muscular atrophy, especially involving the small muscles of the hands and feet, and weakness of the flexors of the fingers and the shoulder girdle muscles. She also had some slight ankylosis

of the joints of the wrists and ankles. A diagnosis of multiple neuritis or neuromyeloradiculitis was made at the hospital.

The patient was rather emaciated and walked with a pronounced steppage gait. Positive observations included advanced generalized muscular atrophy, bilateral foot drop and wrist drop, and inability to close the hands or abduct the arms. There was considerable tenderness on compression over the muscles of the lower extremities. No definite sensory changes were noted; the vibration sense was reduced to one eighth normal; there was general areflexia.

Fever therapy and vitamin B complex given orally in teaspoon doses three times daily brought improvement in appetite, relieved the muscle tenderness and made walking easier and possibly also influenced muscle strength for the better. There was no appreciable change in the muscular atrophy, however. December 7 she was placed on wheat germ oil and vitamin B mixture in a proportion of 1:8, in teaspoon doses three times daily. She rapidly responded to the change in medication. She felt stronger physically, gained weight and was able to do more without becoming exhausted. Regeneration of the atrophied musculature also became apparent at the end of one month. Two months later the hand grip had nearly returned to normal and the atrophy of the interossei has become much less prominent. The foot drop, the steppage gait and the wrist drop have nearly disappeared.

Case 6 is of interest because of the improvement in the neuritic symptoms on vitamin B complex therapy, but without rapid change for the better in the muscle atrophy. The addition of the wheat germ oil acted apparently as a stimulus to muscle regeneration, with the concomitant return in muscle bulk and strength.

CASE 7.—A girl aged 9 years, first seen on Oct. 25, 1939, complained of difficulty in walking because of weakness of both legs, pain in the lower extremities on exertion, and some muscle atrophy in both thighs. The present condition came on after an attack of anterior poliomyelitis in August 1939, which produced involvement of both lower extremities and necessitated bed rest for a number of weeks.

The patient was slightly obese. She walked with an unsteady gait and was unable to stand up alone unless supported. She was unable to rise from a lying to a sitting position without assistance. There were bilateral atrophy and weakness of the gluteal, iliopsoas and quadriceps muscles. The circumference of the left leg and thigh was 1 inch greater than on the right. The abdominal muscles were weak and flabby. Flexion of the right thigh was 20 degrees and of the left 40 degrees. Leg extension on the thigh was reduced on the right to 30 degrees and on the left to 40 degrees. There was tenderness on slight compression of the muscles of the lower extremities. No sensory changes were noted. There was bilateral absence of the ankle jerks; the knee jerk was not elicited on the right and was very sluggish on the left.

On vitamin B complex the patient showed definite gain in that pain completely disappeared. She was able to walk without support, and extension of the leg and flexion of the thigh also improved. The muscle atrophy, however, had not changed appreciably.

In December she was placed on wheat germ oil and vitamin B mixture. The response was very satisfactory. One month later muscle function had nearly returned to normal, the limp had also greatly improved and the evidence of muscle atrophy was not discernible any longer. As far as can be determined this patient has escaped any serious after-effects from the attack of poliomyelitis which she had in August 1939.

COMMENT

The substance (or substances) found in wheat germ oil, at present designated as vitamin E, is probably akin in nature to the vitamin B complex and is composed of many factors, each having its own sphere of influence on the processes of growth and metabolism. The ability of the organism to utilize what it needs and discard the excess as unnecessary substances explains why so many pathologic conditions are relieved by the admin-

istration of all the factors in a certain vitamin, even if some of the factors are not actually needed. After further analysis of the essential therapeutic properties of the vitamin complex it will be possible to prescribe the individual factor required to cure a certain deficiency state. In the meanwhile, however, till this stage of knowledge is gained, the use of the entire vitamin complex should not be considered superfluous.

The exact part played by vitamin E in the process of proteolysis and its influence on muscle metabolism has not been fully determined yet. Meldolesi's² assumption that insufficiency of proteolytic enzymes in the blood was the cause of muscular dystrophy is given added weight by Shute's⁸ observation of antiproteolytic substances in the blood serum of patients with abruptio placentae and threatened abortion. The fact that both the dystrophies and the states of threatened abortion are relieved by administration of wheat germ oil (vitamin E) would imply the possibility that in both instances the activity of the vitamin is inhibitory to the antiproteolytic substances in the blood serum which by their activity interfere with normal metabolism of protein and its transformation into normal muscle tissue.

Vitamin E probably acts also as a stimulus to cell proliferation in muscle cells in the same manner as it acts on the testes of experimental animals.⁹ The rapid regeneration of atrophied muscle was especially evident in cases 6 and 7, in which considerable muscle atrophy occurred following polyneuritis and anterior poliomyelitis, but with rapid return to normal after administration of vitamin E. In this way it differs from vitamin B, which is primarily concerned with nervous tissue metabolism, and this would explain the slow muscle regeneration which occurred in patients 6 and 7 while they were receiving vitamin B complex alone.

The relationship of the vitamin E complex to the endocrine system offers a field for fruitful investigation. The more than accidental concurrence of muscular dystrophy with Fröhlich's syndrome or other endocrine disturbances brings up the relationship of some constituents of the vitamin E complex to cells in the hypothalamus and the pituitary body controlling gonadal function and fat metabolism. The connection of sterility with muscular dystrophy as seen in dystrophia myotonica assumes new significance in view of Shute's¹⁰ report of treating successfully certain cases of sexual maldevelopment with vitamin E. It would especially deserve a therapeutic trial in dystrophia myotonica because of involvement in such patients of both the muscular system and the gonads. Although muscular dystrophies are more common in the male and most often transmitted through the female, there is a possibility that a number of pathologic disturbances in women which are at present ascribed to other causes are actually the result of vitamin E deficiency.

The administration of wheat germ oil as a prophylactic measure to pregnant mothers of dystrophic families also deserves a clinical trial. In the past birth control or sterilization was the only solution. It should also be given a therapeutic trial in cases of muscle atrophy secondary to damage to the anterior horns of the cord or peripheral nerves, namely multiple neuritis,

anterior poliomyelitis with muscle atrophy, amyotrophic lateral sclerosis, and progressive muscular atrophy. The combination with the antineuritic vitamin B complex should increase its therapeutic value in such cases.

SUMMARY AND CONCLUSIONS

Five patients with muscular dystrophy, one patient with muscular atrophy following anterior poliomyelitis, and one patient with muscle atrophy after an attack of multiple neuritis or neuromyeloradiculitis were treated with vitamin E (wheat germ oil).

Definite improvement was obtained in all cases with muscular dystrophy, the improvement being manifested in gain in muscle strength, the disappearance of fatigue and muscle pain on slight exertion, change in muscle texture, and displacement of dystrophic musculature by normally contracting muscle tissue.

In the cases of muscular atrophy following involvement of the nervous system, increase in amount of regeneration of muscle tissue became apparent after the addition of vitamin E (wheat germ oil) to the vitamin B complex the patients were receiving.

The addition of vitamin B complex to vitamin E appeared to increase the therapeutic efficaciousness of the latter.

There is need for further clinical investigation of the potentialities of vitamin E in the treatment of muscular atrophies and dystrophies.

THE ROLE OF VITAMIN B₁ IN DELIRIUM TREMENS

HUGH E. KIENE, M.D.

ROBERT J. STREITWIESER, M.D.

AND

HIMON MILLER, M.D.

PROVIDENCE, R. I.

Vitamin B₁ has been used in the treatment of peripheral neuritis of alcoholic origin with encouraging results. Prior to the recognition of the role played by vitamins, polyneuritis in the alcohol addict was usually attributed to the direct toxic action of alcohol. Since Shattuck¹ in 1928 first called attention to the occurrence of beriberi in persons with chronic alcoholism, syphilis, carcinoma and chronic debilitating diseases, the term "alcoholic polyneuritis" gradually discarded in favor of a more inclusive and general conception.

Since the work of Shattuck, Wechsler² and Minot³ and his associates⁴ have pointed out that avitaminosis probably plays an important role in the production of this type of polyneuritis. Goodhart and Jolliffe⁵ reached the conclusions that (a) vitamin B₁ deficiency is the primary cause in the alcohol addict, and (b) improvement in the objective signs of polyneuritis of this form varies directly with the vitamin B₁ intake up to the point of optimum dosage.

It is notoriously true that many chronic alcohol addicts consume an irregular and inadequate diet and

consequently the total intake of vitamin B₁ is insufficient. In addition, Ornstein⁶ points out that, even though the chronic alcohol addict may ingest a sufficient amount of vitamin B₁ for his caloric intake in the form of food, each calory received in the form of alcohol decreases the total intake of vitamin B₁ and increases the requirements. Thus, regardless of food intake, the chronic alcohol addict has an inadequate vitamin consumption. According to New and Nonofficial Remedies,⁶ 200 international units of vitamin B₁ is needed in the daily requirements. Cowgill⁷ states that according to his formula, on an average, an individual weighing 75 Kg. (154 pounds) needs 280 international units a day. Bowman and his co-workers⁸ have made the valuable suggestions that the factors contributing to delirium tremens are "infections, lowered chloride content of the blood, lowered vitamin reserves, increased lactic acid in the blood and psychogenic factors." Cline and Coleman,⁹ in a review of the etiology of delirium tremens, have given various other contributors' points of view, one stating that delirium tremens has never occurred except when alcohol has been abruptly withdrawn. We are likewise convinced that this is an erroneous assumption because of observations in our two series.

It is our contention that the cause of delirium tremens is essentially a vitamin B₁ deficiency which has been brought on by sudden deficits in the maintenance requirements. Inadequate, irregular and at times total abstinence of diet is practically universal in acute delirium tremens. The person so affected usually does not stop for adequate dietary foods in his alcoholic meanderings after the first twelve hours. This point has been closely checked in each patient's history presented in this series.

Approximately 70 per cent of all patients with acute delirium tremens who were admitted to this service have complained on entrance of nausea and symptoms of gastritis, stating in a universal language "Take it away! The sight of food makes me sick!" Anorexia itself has been established by many other investigators as a result of deprivation of adequate vitamin B₁. Russell¹⁰ has reported three cases in which, after a single subcutaneous injection of 400 international units of crystalline vitamin B₁, the patients' appetites have returned within twenty-four hours "to such an extent that it was difficult to satisfy their desire for food." In our series of cases it was found that the persons receiving intravenous vitamin B₁ had regained the desire to eat within twenty-four hours while those not receiving this treatment took approximately twelve to eighteen hours longer.

Alcohol in small amounts may cause an increase in appetite, but when it is taken in large quantities over a prolonged period the appetite is lost. This lack or loss of appetite results in a relative food loss with attending vitamin B₁ deficiency and later may result in peripheral and central (cerebral) neuronitis.

It is felt that the delirium tremens is an irritative stage of the central (cerebral) neuronitis having its mechanism of function as a disturbance in the relation-

From the Charles V. Chapin Hospital.

The intravenous vitamin B₁ (Betaxin) was furnished by the Research Department of the Winthrop Chemical Company, Inc.

DELIRIUM TREMENS—KIENE ET AL.

2192

ship of a deranged carbohydrate and vitamin B₁ metabolism. This irritative phenomenon can and does occur many times in an alcoholic individual before a permanent neuron destruction occurs, as is later shown in the symptoms and other features of Korsakow's syndrome and in the absent knee jerks of far advanced peripheral neuritis of this origin. It is conversely true that many alcoholic patients, including those having had many bouts of delirium tremens, do not develop Korsakow's syndrome or peripheral neuritis. For this fact an explanation is offered that individual variations in vitamin B₁ consumption and absorption do exist as well as ability to consume alcohol, some of which may not be of the best brand.

In this paper we present ten cases of delirium tremens treated at the Charles V. Chapin Hospital in the past year. All patients were selected by a standard insisting that (a) vivid hallucinations of alcoholic origin must have existed at the time of entry; (b) a history

4. Routine nursing care was given, keeping the patient clean, preventing injury, assuring food intake and caring for excretory functions and the forcing of fluids.
5. Each patient was weighed on entry and at discharge.

In the five control cases:

1. No whisky was given.
2. Intravenous vitamin B₁ was not given except to patient 6, who received only 30 mg.
3. The same ward diet was followed with supplementary vitamin B₁ to insure that at least the ordinary daily requirements were met.
4. The identical consideration and nursing care were administered.
5. Each patient was weighed at entry and at discharge.

The five patients who received whisky and intravenous vitamin B₁ showed an almost immediate improvement in the physical and mental status. The generalized dehydration and some roughness of skin, which were noticed on entry, cleared within twenty-four to thirty-six hours after admission. Also the patients were still receiving a minimum of 32 ounces (950 cc.) of whisky every twenty-four hours. The visual hallucinations and fear reactions likewise were noticeably lessened and generally nonexistent within thirty-six hours. Restlessness, agitation and generalized motor activity, so frequently seen in delirium tremens, subsided so that continuous baths or chemical restraints were only rarely necessary in these cases.

In the five control cases the duration of time for the symptoms to clear was relatively longer and patient 7 was eight days in a state of acute delirium.

As will be seen in the table, the control patients had an average of 4.2 days before recovery, while the five patients receiving whisky and intravenous vitamin B₁ had an average of 2.4 days. It is interesting to note that a more rapid recovery time is to be expected when concentrated doses of vitamin B₁ are given intravenously. The total number of hospital days of the first series was half that of the control group. It is also observed that the weight gain was more in the control group than in the treated group. The explanation offered for this is that the control group, availing themselves of a continued balanced vitamin diet. It will be seen by examining the total milligram amount and the total international unit amount in both series that the original group received on an average per person 74.9 times more international units than the daily required. The control group in their diets received adequate daily requirement consisting of 528 international units, which is practically double the minimum amount (154 pounds [70 Kg.] requires 280 international units[†]).

The following report is a brief summary of each of the ten cases under consideration:

REPORT OF CASES

CASE 1.—An unmarried laborer aged 42, weighing 146 pounds (66 Kg.), was admitted to the psychiatric ward for the third time on Dec. 8, 1938. According to the admission paper he was extremely nervous, was profane and suffered delusions of persecution and homicidal tendencies. The cause of his symptoms was alcoholism.

On admission the patient was in good general physical health. There was a strong odor of alcohol on his breath and he was tremulous, being unable to stand without support. A heavy trace of albumin and many white blood cells were found in the urine. The blood nonprotein nitrogen was 50 mg. per hundred cubic centimeters and the blood creatinine was 1.5 mg. per hundred cubic centimeters. The icteric index was 5.

Summary of Case Reports

Case No.	Hospital Days During Delirium	Total Hospital Days	Weight, Lb.		Gain or Loss	Total Intravenous Mg. of Vitamin B ₁	Total International Units*
			On Admission	On Discharge			
1	3	6	146	154	+ 8	200	67,570
2	3	15	188	191	+ 3	525	175,620

of periodic overindulgence in alcohol and inadequate food consumption was given, and (c) a consumption of alcohol in some form had continued up to the time of hospital entry. Except for hallucinations, acute toxic symptoms, generalized tremor and roughness of the skin, all patients were in satisfactory physical condition, unless it is specifically stated otherwise. Five of them were treated with various amounts of intravenous vitamin B₁ and whisky, while the remaining five were used as controls with symptomatic therapy and with no unusual emphasis on vitamin intake.

The method of treatment used in these five cases was as follows:

1. Four ounces (120 cc.) of bonded rye whisky was given every three hours commencing on admission so that there would be no time during which the patient was not receiving alcohol. The whisky was given to prove that the intake of alcohol was not responsible for the patient's delirium tremens.
2. Synthetic crystalline vitamin B₁ was given intravenously (50 mg. or more) in a period of twenty-four hours.
3. Daily ward diets containing at least 209 international units of vitamin B₁ and supplementary vitamin B₁ in the form of yeast and vitamin capsules were given in some cases to insure adequate vitamin content.

On mental examination he vividly described visual hallucinations, remarking "I got delirious tremens." What do you see? "Pink elephants, brown elephants, polar bears, Rhode Island reds, alligators—if I was to tell you, I would say the whole Barnum and Bailey outfit—every animal he has got." Have you ever been delirious before? "Yes, twice." He was oriented as to time, place and person and recognized several staff members whom he had seen before.

The social history indicated prolonged and excessive indulgence in alcohol of all grades.

Treatment consisted of 4 ounces of whisky every three hours, 25 mg. of vitamin B₁ given intravenously twice a day and a high caloric diet.

On the second hospital day urinalysis was practically negative, and on the fourth day it was completely negative. Several later examinations were also reported as negative. The blood nonprotein nitrogen was 43 mg. and the blood creatinine was normal at the end of the second hospital day.

The night of admission 3 grains (0.2 Gm.) of pentobarbital sodium was given twice because of extreme restlessness and he later had to be awakened to receive the prescribed doses of whisky. The following day he was cooperative but still tremulous and showed marked unsteadiness of gait. He mumbled considerably to himself and perspired freely. General improvement marked the third hospital day. The tremor was lessened and his general well-being was commented on by the patient himself. The whisky was increased to 4 ounces every two hours and discontinued late that same night. The vitamin B₁ was discontinued at the end of the fourth hospital day.

The patient was discharged on the sixth hospital day free from all hallucinations and left with a sense of well-being and with a weight gain of 8 pounds (3.6 Kg.).

CASE 2.—An unmarried factory worker aged 24, weighing 188 pounds (85 Kg.), was admitted for the first time to the psychiatric service because of visual hallucinations and a generalized convulsive attack which took place as he was taking a bath. There was a history of drinking for the past two years but of no previous hallucinations.

On admission the patient was in good general physical condition except for a heavy trace of albumin and rare granular casts in the urine; the temperature was 101.8 F. rectally and the pulse rate 150 with normal blood chemistry.

Mental examination revealed definite ideas of reference and paranoid delusions. "People are hiding in this room. They're trying to do me up. My people have all poisoned themselves." Visual and auditory hallucinations were clearly demonstrated in the patient's actions. He declared emphatically that he could see trees in the room and that lampposts were walking around and spitting at him. He complained bitterly that soldiers were marching up and down in the halls and when passing his room would try to fire on him. On one occasion while looking out of the window the patient suddenly began to cry, saying "there's a little boy out on the lawn with both legs cut off and nobody is around to help him." Generalized excitement was so prominent at that time that it was necessary to isolate the patient completely.

Treatment was instituted immediately after entry. He received the customary 4 ounces of whisky every three hours and 175 mg. of vitamin B₁ intravenously, which was given in split doses, each split dose being given at the height of each of four excitement periods. The next day his temperature was normal but tachycardia with a rate varying from 100 to 140 persisted. The same amount of whisky and vitamin B₁ was given. The patient's general excitement started to subside, and on the third day the temperature and pulse were normal. The urine was completely normal, and at the end of the third day all mental symptoms were nonexistent. This terminated the active treatment.

Of special interest in this case was the fact that no chemical restraint of any kind was used during the acute stage of excitement. Vitamin B₁ was repeated in small doses at the height of the excitement. Physical and mental recovery progressed as rapidly as if sedative drugs had been used in the routine manner.

The patient was discharged on the fifteenth hospital day, weighing 191 pounds (87 Kg.).

CASE 3.—An unmarried Irish-American office worker aged 33, weighing 180 pounds (82 Kg.), was admitted to the psychiatric ward for the first time, the admission paper remarking that the patient had hallucinations and thought men were chasing him and that he was destructive, the present symptoms being due to excessive indulgence in alcohol.

On admission his general physical status was good. The urine and blood were essentially normal. Mentally he showed marked evasiveness when questioned about his imaginations, remarking "They're all right. I told the doctor I had them but I didn't. I told him I had a lot of things. I heard cracks all about myself. I had the 'shakes' all right. The doctor asked me if I saw anything but I told him I hadn't seen anything but I heard a lot of things. People were talking about me; everybody's been ribbing me. They said I was a crook and a murderer." Observation in the ward revealed that he was communicating with some one by Morse code and at other times would gesticulate and stare as if he were carrying on active hallucinatory experiences; however, when asked about these he emphatically denied hearing voices or seeing visions. It was interesting to note that he would repeatedly ask attendants and nurses if they were calling him.

The social history disclosed that he started to drink beer in college because a doctor told him it would relax his nerves. This gradually became a habit with him and at the time of entry he was drinking anything he could obtain. There was no history of previous alcoholic psychoses.

Treatment consisted of the usual 4 ounces of whisky every three hours, 25 mg. of vitamin B₁ intravenously twice a day and the house diet.

Active mental symptoms continued for two days and nights. On the second night he was very resentful and irritable, almost refusing to take the prescribed amount of whisky and answering the nurses' requests with "What the h— do you fellows intend to do to me? Have I got to take this stuff and see things again tonight?" The mental symptoms appeared to clear completely overnight and he was discharged on the fourth hospital day. The whisky and vitamin B₁ had been prescribed for three days and two nights. At the time of discharge there was a weight gain of 2½ pounds (1 Kg.).

CASE 4.—An unmarried Irish-American gas station attendant aged 31, weighing 168 pounds (76 Kg.), was admitted to the psychiatric ward for the first time, the admission paper stating that he had been having hallucinations due to excessive indulgence in alcohol.

Physical examination was essentially negative except for a pulse of 110 and a generalized tremor. The laboratory data were normal. Mentally he was cooperative but complained of seeing rats chewing paper on the floor in his room, men walking on the walls and strange animals walking around his room and going in and out of the window. He was expansive at times and remarked "I saw the World War reenacted today in Fall River. Fifty thousand people were shot down and even the women were fighting." He was confused and disoriented. There was a history of steady drinking for the previous two years.

The treatment of whisky was started and 25 mg. of vitamin B₁ was given intravenously twice a day with the regular house diet. In addition at least 40 ounces (1.2 liters) of fruit juices and six tablets of brewers' yeast were given.

On the second hospital day he was correctly oriented, very cooperative and remarked that he had gotten over the "horrors" and was not seeing anything. The third day he appeared intoxicated and remarked "I had \$2.50 when I entered the hospital and the guys around here must have rolled me for it." In a few hours he had lost this paranoid reference and said no more about it. He was completely oriented in the evening of this same day and all medication was stopped. Although his appetite was excellent the patient had lost 5 pounds (2.3 Kg.). On the following day he was discharged.

CASE 5.—A white man aged 49, divorced, weighing 140 pounds (64 Kg.), was admitted to the psychiatric ward for the first time on Aug. 28, 1939, for the treatment of delirium tremens. On

admission he was markedly restless, impulsive and unpredictable and had to be restrained. He was actively hallucinating and disoriented with rambling, disconnected speech and complained bitterly of bugs crawling over his body and in his ears.

Physical examination revealed nothing remarkable except that both ears were discharging some semipurulent material, a condition which was later diagnosed as chronic nonsuppurative otitis media. Laboratory data were essentially normal.

The social history revealed heavy indulgence in liquor for the previous eight years, the patient at times drinking as much as a quart daily. No previous history of auditory or visual hallucinations was obtained.

Treatment consisted of whisky, 4 ounces every three hours, and 50 mg. of vitamin B₁ given intravenously twice a day. Within twenty-four hours the active mental symptoms had subsided. Whisky and vitamin B₁ were then discontinued after his having received 100 mg. The only complaint registered was pain in the arms.

On the third day all symptoms of an alcoholic nature had subsided completely. The usual tremor and unsteady gait had disappeared and he seemed very grateful for having "come through the horrors." He was discharged on the sixth hospital day and was referred to the ear clinic for treatment of his otitis media. The weight gain was 18 pounds (8 Kg.).

REPORT OF CONTROL CASES

In the control series we have a group of five cases of delirium tremens in which routine symptomatic therapy was given as previously described:

CASE 6.—A white man aged 43, married, weighing 144½ pounds (66 Kg.), had been drinking periodically for years and heavily for four days before entry. On the physical examination hypertension with blood pressure of 160 systolic, 90 diastolic, was noted. The blood Wassermann reaction was reported 4 plus. The spinal fluid Wassermann reaction was negative. The patient manifested typical visual and auditory hallucinations and delusions of persecution. He received 10 mg. of vitamin B₁ intravenously daily, and recovery from his alcoholic illness was noted in three days.

CASE 7.—A man aged 32, unmarried, weighing 125 pounds (57 Kg.), had been drinking for two years and gave a history of delirium tremens once in the past. Physical and laboratory examinations were essentially negative. Mentally he manifested the usual visual and auditory hallucinations, some buzzing in the ears, delusions of homosexuality and marked preoccupation and seclusiveness. Treatment consisted of the ward diet, and strict attention was paid to his seclusiveness. He recovered in eight days. The weight on discharge was 134 pounds (61 Kg.).

CASE 8.—A white man aged 32, unmarried, weighing 152 pounds (69 Kg.), had been drinking for three years. On entrance he had a mild hemolytic streptococcus sore throat with a temperature of 103 F. This persisted for thirty-six hours with a pulse of 130, after which the temperature and pulse became normal. Respirations were labored; his face was flushed, the finger tips cyanotic. These signs persisted for forty-eight hours. The sight of food appeared to distress him and he complained vigorously of a very poor appetite. In addition to the ward diet he received two tablets of brewers' yeast three times a day. He recovered from his delirium tremens in four days. The throat culture was negative in four days and on discharge (on the twentieth day) he weighed 153 pounds (69 Kg.).

CASE 9.—A white man aged 42, divorced, weighing 150 pounds (68 Kg.), gave a history of drinking for twenty years with exacerbations of delirium tremens on many occasions. Physical examination and the usual laboratory tests were negative. He was placed on a ward diet and recovered in four days. The weight at the time of discharge was 156 pounds (71 Kg.).

CASE 10.—A white man aged 53, divorced, weighing 134 pounds (61 Kg.), was admitted for the second time. There was a history of drinking for many years; on the previous admission to this hospital for delirium tremens he had recovered in three days. On this admission he had all the cardinal symp-

toms of delirium tremens and in addition thought he was a rain maker, calling on God to make it rain. His overactivity and symptoms of hypomania made him a nuisance and he was kept in strict isolation. On ward routine he recovered in two days. After eleven days he weighed 140 pounds (64 Kg.).

COMMENT

In cases 1 and 2 the presence of albumin and hyaline casts was noted. Both patients received whisky and intravenous vitamin B₁ treatment. Yet within seventy-two hours the urine was negative for albumin and casts. Rechecks at the time of dismissal substantiated these observations. Apparently when vitamin B₁ is given, whisky in large amounts does not continue to be a kidney irritant. It is felt that the vitamin B₁ acted directly on the kidneys in a therapeutic way along with routine hydration.

It was not possible to measure vitamin B₁ excretions through the kidneys during this study. Although the patients receiving the intravenous vitamin B₁ had been receiving on an average about seventy-five times the daily requirements during their acute illness, an assumption of how much was utilized by the brain and other structures cannot be ventured except to say that at least a small percentage appeared to be of help. The rapidity with which symptoms cleared would substantiate this when the cases are compared.

Our primary purpose in this paper was to prove that alcohol is not the principal factor in the production of delirium tremens and that a deficit of vitamin B₁ content in the brain parenchyma is chiefly responsible. A central (cerebral) neuronitis, an irritative phenomenon, is caused by a perverted carbohydrate and vitamin B₁ relationship, which when treated with adequate vitamin B₁ responds more remarkably (as far as subsidence of symptoms is concerned) than do the peripheral states of polyneuritis of alcoholic origin.

The question may arise from this work as to whether the intravenous vitamin B₁ or the balanced vitamin diet is the essential part of the treatment. This diet was considered adequate and rich in all vitamins and on analysis over a period of a week averaged 209 international units of vitamin B₁ daily in a total of 2,250 Gm. of food.

Alcohol in the presence of large amounts of intravenous vitamin B₁ does not cause a continuation of the symptoms of delirium tremens. A supplementary observation was that, if adequate vitamin B₁ was given when alcohol was abruptly withdrawn (control cases), eventual recovery would also occur. The fact that recovery from acute symptoms occurred practically twice as fast when intravenous B₁ was given (even in the presence of continued drinking) would indicate an etiology of primary B₁ deficiency in the presence of a deranged carbohydrate metabolism.

Hepatic Lesions.—The liver has been aptly described by Mann as the "commissariat of the body." Its role in maintaining a constant supply of utilizable food materials for the body tissues requires the participation of hepatic activity in every phase of metabolism. The liver is, in addition, the site of many syntheses; it is also an organ of detoxication, secretion and excretion. From these considerations it would be logical to infer that disease of the liver would be revealed quite readily by impairment of some particular function or functions, and indeed it can be shown that hepatic lesions, if severe enough, are accompanied by disorders of glycogen synthesis and storage, fat and amino acid metabolism, secretion and excretion of bile and many other chemical and physical processes.—Bodansky, Meyer, and Bodansky, Oscar: *Biochemistry of Disease*, New York, Macmillan Company, 1940.

WEIL'S DISEASE (LEPTOSPIRA ICTERO-HAEMORRHAGIAE) IN HAWAII

ITS SERUM TREATMENT
SEIGO TOKUYAMA, M.D.
FUKUOKA, JAPAN

Twenty-eight years after the description by Weil in 1886 of a disease characterized by the four cardinal symptoms fever, muscle pains, hemorrhage and jaundice,¹ Inada and Ido in 1914 demonstrated a spirochete as the causative organism.² They also succeeded in curing this disease by serum therapy.³

According to Inada and Ido,³ as soon as the condition has been diagnostically determined the serum treatment should be applied in order to obtain the best results, and a higher rate of recovery accompanies early serum injections. When the serum treatment is given within five days of the disease, recovery is almost certain. Within two to three hours after the treatment

tion and especially muscular pain along his lower limbs which confined him to bed, as he was unable to walk.

Just seven days before the onset of this disease, in order to get some bait for fishing, he went into a creek and got his entire body wet. At that time he had a small wound on his left heel. His family history and past history were non-contributory except for a case of bronchial asthma in his early years.

Physical Examination.—On the fifth day of the disease, when he was admitted, the patient was muscular and possessed a well nourished constitution, yet he lay in bed passively. He suffered pain in moving the eyeballs. The conjunctival vessels were all intensively injected, and slight yellowish changes were seen on the bulbar conjunctiva. His skin was yellow and he was damp with perspiration. There were no exanthems or edema, but a few swellings caused by lymph glands appeared in the left inguinal region. The temperature was 98 F.; the pulse showed a frequency of from 120 to 130 per minute and was feeble but relatively larger, with an arrhythmia. The apex beat of the heart could not be perceived. By percussion the area of cardiac dullness was found to be enlarged a little to the left side, and on auscultation the heart sounds were very weak, murmuring and arrhythmic and showed embryocardia. The

Summary of *Leptospira Icterohaemorrhagiae* Cases Treated

Patients 7 and 8 did not recover after serum injection, owing to its lateness.⁴

with 20 cc. of serum, the causal organism found in the blood almost vanishes.

During the past two decades, numerous cases have been reported in European and Japanese medical journals as mentioned,⁴ but I have not been able to find reports on this serum treatment in Hawaii. Through one of my friends, I was given a chance to use the serum for *Leptospira icterohaemorrhagiae* in treating the disease here. This has encouraged me to report my cases.

The two following cases are examples of the disease with and without the serum treatment; ten other cases are also listed in the accompanying table.

CASE 1.—History.—T. O., a fisherman aged 47, was admitted to the Japanese Hospital in Honolulu Oct. 31, 1927. There had been no particular sign of trouble until early in the morning of October 27, when the patient suddenly suffered from a chill with headache, dizziness, anorexia, fever, prostra-

second pulmonic sound was strongly accentuated. The liver could be palpated two fingerbreadths below the costal margin in the median line and was distinctly tender, intensive pain being elicited by pressure. The spleen was also palpable yet not so tender. Albumin, diazo and bile reactions in the urine were positive, but Fehling, Wassermann, Kahn and Widal reactions were all negative. Leukocytes numbered 9,260, with polymorphonuclears 92 per cent, lymphocytes 2 per cent and myelocytes 6 per cent; erythrocytes numbered 32,000,000 and the hemoglobin content was 80 per cent.

Course.—On October 31, the fifth day of the disease, the patient's temperature was about 100 F., but he complained continuously of headache and prostration in spite of the subcutaneous injection of 1,000 cc. of physiologic solution of sodium chloride and all kinds of heart tonics.

A smear seen under the microscope proved that *Leptospira icterohaemorrhagiae* was the causative organism. Therefore 2 cc. each of the patient's blood was inoculated into the peritoneal cavities of three guinea pigs. On the sixth day of the disease, jaundice seemed to increase. Gradually drowsiness and anuria were added to the disturbances mentioned. On the seventh day the patient's temperature ranged between 99 and 100 F. From his admission until this day the pulse rate ranged from 120 to 150. The intensity of jaundice increased greatly. On smears no spirochetes could be perceived. On the eighth day the temperature became subnormal and jaundice became

Prof. H. Takeya and R. Kaneko of the Kyushu Imperial University reviewed this report.

more intense. Petechiae on the costoabdominal region and on the lower limbs were distinctly seen. By microscopic examination the causative organism could not be found. On the ninth day, diarrhea with profuse hemorrhage was observed several times. Next day the patient's condition was very critical; petechiae (i. e. hemorrhage) increased gradually and became severe. On the twelfth day the patient died under toxic conditions. All the clinical and microscopic evidence confirmed the diagnosis of spirochetosis icterohaemorrhagica.

Guinea Pig Inoculation.—As has been mentioned, on the fifth day of the disease, after it had been proved microscopically that a spirochete was the cause, 2 cc. each of the patient's blood was inoculated intraperitoneally into three guinea pigs.

Guinea Pig 1: On the tenth day after inoculation, the fourth day of the disease, the guinea pig became intensely yellow. The skin was also deeply tinged and the animal seemed very sick. It died on the fifth day of the disease. Autopsy was performed. *Leptospira icterohaemorrhagiae* was found in the emulsions of the liver and the spleen.

Guinea Pig 2: On the eleventh day after inoculation, the fifth day of the disease, the animal showed jaundice and anuria. On the following day it died, and autopsy was performed. The results were the same as for guinea pig 1.

Guinea Pig 3: Results similar to those for guinea pigs 1 and 2 were found. However, the causal organisms could not be observed in the blood, urine or tissues.

Two cc. of blood from the heart of guinea pig 1 was inoculated into guinea pig 4 for further study, but the results were similar to those for guinea pigs 1, 2 and 3.

CASE 2.—History.—A gardener aged 43 entered the Japanese Hospital in Honolulu on Oct. 10, 1928. His family history and past history were not remarkable, but he had always been well. At midnight of October 8 the patient was seized with a rigor, and his temperature rose suddenly to 103 F. He suffered from lassitude, headache and gastric distress such as nausea and vomiting, with accompanying dizziness, prostration and intensive gripping pain in the back and especially in the calf muscles. On the first examination the appearance of jaundice and also marked nervous manifestations were observed. He lay in bed passively.

Here too it was interesting to note that six days before the onset of this disease the patient went into the creek water and stayed there for several hours in order to fish, but according to him there had been no visible wound on his body.

Physical Examination on Admission.—The patient was admitted on the fifth day of the disease after a physical examination which showed that he was poorly nourished. He lay in bed passively. Incidentally, he seemed comparatively young for his age. He complained of intense pain in moving the eyeballs, and the conjunctival vessels were all intensely injected. The scleras showed a fairly yellow discoloration, and possibly there was a slight yellowish tint to the skin. There were no exanthems or edema, but in both inguinal regions a few swollen lymph glands were easily recognized. The liver and the spleen were enlarged and palpable, though not tender. A tendency to hemorrhage as shown by epistaxis and petechial eruptions was seen. The temperature was 102 F. and the pulse rate of over 130 per minute was of the genuine febrile type. The heart conditions also were not quite normal, the second pulmonic tone being strongly accentuated.

The albumin and diazo as well as bile reactions in the urine were positive to a considerable degree, but the Fehling, Wassermann, Kahn and Widal reactions were all negative. Leukocytes numbered 9,600. Two cc. of the patient's blood was inoculated into the peritoneal cavity of each of three guinea pigs. All the pigs afterward gave positive evidence of the routine causative organisms, as described in the report of case 1. Thus at the time of entrance to the hospital the evidence pointing to Weil's disease was very clear, and I had little doubt of the diagnosis.

In accordance with the diagnosis, 40 cc. of Inada and Ido's serum of *Leptospira icterohaemorrhagiae* was intravascularly injected at intervals of twenty-four hours, strictly according to their instructions; i. e., 1 cc. of this serum was injected three hours before the second 2 cc. injection; this serum was warmed

to 37 C.; injections were administered as slowly as possible—in not less than five minutes. The injection of this serum produced brilliant effects. Several minutes after the first injection the patient was seized with a chill lasting for half an hour, and about six hours later his general improvement was striking. On the next day the muscular pains greatly diminished and the marked nervous manifestations subsided almost completely. Jaundice and petechial eruptions also disappeared gradually. Thus day by day he recovered more rapidly, convalescence lasting two weeks without the usual prostration.

The other ten cases showed great similarity in the clinical conditions at the inception of the illness. Therefore, to avoid repetition, I have summarized all the cases which I treated in the accompanying table.

SUMMARY

1. Twelve cases of hemorrhagic spirochetal jaundice were observed in Hawaii, the diagnosis being confirmed clinically in two cases and bacteriologically in nine cases. The disease was proved to be identical with that occurring in Japan by both clinical and bacteriologic criteria.

2. Nine of the twelve patients were inoculated with the *Leptospira icterohaemorrhagiae* serum of Inada and Ido; seven of the inoculated patients were cured and two died. Death was due to the lateness of the serum injection.

3. Three of the patients did not receive the serum; of these two died but one recovered.

Clinical Notes, Suggestions and New Instruments

ACUTE POLYRADICULONEURITIS (GUILLAIN-BARRÉ SYNDROME)

A CLINICAL REPORT OF TWO CASES

TREODORE T. STONE, M.D., PH.D., AND KNIGHT ALDRICH, M.D.
CHICAGO

Our purpose in this communication is to call attention to the fact that in order to make an accurate diagnosis of the Guillain-Barré syndrome it may be necessary to do more than one spinal puncture to determine the presence of the characteristic albuminocytologic dissociation. We are reporting two such cases.

As far as we could determine, none of the contributors (Guillain,¹ Bassoe,² Gilpin, Moersch and Kernohan,³ Van Bogaert and his co-workers,⁴ Gillespie and Field⁵ and many others) to this syndrome have emphasized or even mentioned such a fact. Guillain⁶ has insisted that this albuminocytologic dissociation be absolutely present before making a diagnosis of this disease. In 1916 he, in collaboration with Barré and Strohl, called attention to a clinical syndrome "characterized by motor disturbances, loss of tendon jerks with preservation of cutaneous reflexes, paresthesias with slight disturbance of objective

sensibility, tenderness on pressure of the muscles, little change in the electrical reactions of the nerves or muscles and noteworthy hyperalbuminosis of the cerebrospinal fluid in the absence of cytologic reaction." Madigan and Marietta⁷ in 1938 stated that the increased total protein may be transitory or absent. They report a case in which the first spinal puncture showed 18 mg. of protein while the second showed 122 mg. of protein in the spinal fluid.

CASE 1.—*Motor weakness, multiple cranial nerve palsies, absent deep reflexes, paresthesias, muscle tenderness, partial reaction of degeneration with normal spinal fluid. With progression of symptoms in the hospital a second spinal puncture revealed an albuminocytologic dissociation.*

C. B., a man aged 46, white, a laborer, admitted to the hospital in Dr. Stone's service on March 16, 1940, stated that he had had a cold for two weeks, starting with abdominal pain and developing into a cough, but had otherwise been well until March 14, when on getting up in the morning he felt dizzy, his legs gave way and he fell to the floor. Later in the day his hands felt numb and the following day he had difficulty in swallowing food and drink with occasional regurgitation through his nose, and a nasal speech. His temperature on admission was 98.2 F. and blood pressure 120 systolic, 80 diastolic. On physical examination there were no gross abnormalities. The pupils were round and equal and reacted to light and in accommodation. The palate and uvula rose poorly in the midline. All deep reflexes except the radial and ulnar were bilaterally absent and the right abdominal reflex was not elicited. There was marked ataxia in finger to nose and heel to knee tests bilaterally, more so on the left. Sensation was intact except for vibration sense, which was absent bilaterally below the clavicles. The spinal fluid was clear, colorless and under pressure of 10 mm. of mercury with no block; the Pandy test was negative; there were 10 cells per cubic millimeter, 46 mg. of protein per cubic millimeter, both blood and spinal fluid Wassermann reactions were negative, as were routine blood and urine analyses, and a tentative diagnosis of encephalomyelitis was made.

On March 18 there was no movement of the palate or uvula; the tongue deviated to the left; there was a left ptosis and slight limitation in the left lateral gaze. The patient complained of weakness and numbness "all over." The blood nonprotein nitrogen at this time was 40. The following day muscle tenderness in the calves was marked, the knee and ankle reflexes were absent, there was a questionable left Babinski reflex, absent abdominal reflexes and an absent right cremasteric. Hypalgesia was noted up to the level of the fifth thoracic segment bilaterally. There was a left peripheral facial weakness and both lids were ptosed. The only extra-ocular movement elicited was a slight lateral movement of the left eye (which was not present the next day). The pupils reacted sluggishly to light but well to accommodation. There was weakness in both sternocleidomastoids. A course of sulfanilamide was instituted. On March 21 the condition was much the same, save for a bilateral peripheral facial paralysis and slight movement of the left palate. The spinal fluid was clear and colorless and under normal pressure; the Pandy test was markedly positive; there were 2 cells per cubic millimeter and 375 mg. of protein per cubic millimeter.

Sulfanilamide was discontinued on March 25 as the patient was becoming jaundiced and vomited frequently. He complained less of pain in his extremities and could speak and swallow more easily. Two days later, despite the use of Buller shields and frequent irrigations, he developed a small corneal ulcer. At this time he still had bilateral ptosis and facial paralysis but showed a return of motion of 5 degrees in all fields of his right eye.

On March 29 he could close his eyes, the palate rose well in the midline and the tongue protruded in the midline. The ataxia had improved and he could feed himself. On April 2 his facial paralysis had practically disappeared and his general condition was much improved but the reflexes and vibration

sensation were still absent. On April 10 a third spinal puncture revealed 300 mg. of protein per cubic millimeter, a four plus Pandy test and 10 cells. Electrical examination showed a diminished reaction to faradic current (partial reaction of degeneration).

CASE 2.—*Motor weakness, diminished tendon reflexes, paresthesias, muscle tenderness, no change in electrical reaction. The objective signs on entrance were minimal, particularly in comparison with the marked subjective complaints and in the presence of an essentially normal spinal fluid; attention was at first directed away from an organic basis for her complaints. With the appearance of a peripheral facial paralysis, spinal puncture was repeated and albuminocytologic dissociation found.*

A. B., a woman aged 42, white, a housewife, admitted to the hospital in the service of Dr. L. W. Avery on Feb. 22, 1940, stated that on February 18 she first noticed that her legs were becoming progressively weaker and that on the following day she fell on the stairs and had to be assisted to bed. At that time she realized that her arms were weak and she developed numbness of all her extremities. She remained in bed but continued to lose strength until on entrance to the hospital she could not move her legs at all and had markedly weakened grasp with both hands. Her past history was negative save for an attack of weakness of the legs following a fall on the stairs twenty-seven years before which gradually improved over a period of three months. She stated that she had not had a cold. Her temperature on admission was 99.6 F. and blood pressure 128 systolic, 76 diastolic. Physical examination disclosed no gross abnormalities. The pupils were round and equal and reacted to light and in accommodation. Muscle power was weakened in all groups. The deep reflexes were present and normal and there were no pathologic reflexes elicited. The abdominal reflexes were present on the left and absent on the right. Sensation in all modalities was unimpaired. The spinal fluid was clear and under pressure of 13 mm. of mercury with no block; the Pandy test was negative; there were 3 cells per cubic millimeter, 67 mg. of protein per cubic millimeter and both blood and spinal fluid Wassermann reactions were negative. The blood and urine were normal and analysis of the hair and nails for arsenic was negative. The patient's face showed concern and apprehension and she told without much urging a long story of family and economic difficulties. In the ward she continually complained of pains throughout her body, chiefly in her extremities, cried a great deal and insisted without foundation that the nurses, doctors and attendants were discriminating against her. The diagnosis was deferred at this time.

On February 26 she complained of inability to swallow solid food but examination revealed no signs of bulbar paralysis. On February 28 it was noted that her left knee jerk was absent and that the deep reflexes of the upper extremity were greatly diminished. There was no muscle tenderness or sensory disturbances and the electrical reactions were normal. On March 4 she developed a left peripheral facial paralysis and complained of increased muscle soreness especially at night. The spinal fluid on March 5 was clear and under normal pressure. The Pandy test was 2 plus; there were 6 cells per cubic millimeter and the protein 375 mg. per cubic millimeter. At that time there was reported slight movement of both arms. By March 9 she could move her upper extremities well. On March 17 she fed herself for the first time and a marked change was noted in her attitude. She became quite cheerful and optimistic. By March 29 her facial paralysis had practically disappeared and the next day she was able to walk. Examination on April 2 was practically negative. The deep reflexes were bilaterally brisk and equal. On April 17 a third spinal puncture revealed 6 cells, a one plus Pandy test and 90 mg. of protein.

COMMENT

Owing to the fact that development of the albuminocytologic dissociation occurred late in the disease in our two cases it was not possible to diagnose them accurately at first as of the Guillain-Barré type. Since in this syndrome the prognosis is very favorable one readily appreciates the fact that the finding

7. Madigan, P. S., and Marietta, S. U.: Polyradiculoneuritis with Report of Case, *Ann. Int. Med.* 12: 519 (Nov.) 1938.

of the albuminocytologic dissociation is of utmost importance not only in making a correct diagnosis but also in giving a true prognosis.

SUMMARY

In two cases of Guillain-Barré syndrome the albuminocytologic dissociation was found after the second spinal puncture during the course of the illness and not at the onset. Albuminocytologic dissociation may be a late manifestation of this syndrome.

30 North Michigan Avenue.

INTRAVENOUS INJECTION OF PARALDEHYDE FOR THE CONTROL OF CONVULSIONS

I. S. WECHSLER, M.D., NEW YORK

Sometime in 1919, during the early days of epidemic encephalitis, I had under my care one of the most violent hyperkinetic types of the disease, with extreme restlessness, toxic delirium and intractable insomnia. The course was punctuated by repeated clonic and tonic spasms of brief duration. The patient, a young man in the early twenties, was so violent in his restlessness that he had to be restrained almost all the time and required the constant attendance of two nurses by day and night. He was given all sorts of sedatives and hypnotics in large doses without effect. The barbiturates, if anything, only increased the restlessness. Paraldehyde in large doses by rectum had a transient effect, never lasting for more than fifteen minutes at a time. Spinal tap and drainage of fluid did not seem to influence the course. In sheer desperation I tried the intravenous injection of 1 cc. of paraldehyde. This was done with some trepidation since I did not know what effect the ordinary paraldehyde solution would have on the blood; I knew that the solution was sterile, so that there was no fear of infection. By the time the last drop was injected, literally before the needle was withdrawn, the patient quieted down and promptly fell asleep. For the first time in two weeks he slept about two hours. The injection was then repeated, with similar results. This was followed by the administration of 1 cc. of the drug at varying intervals during the twenty-four hours, which was kept up for several days. The patient gradually improved and ultimately recovered, fortunately without any sequelae.

Since then I have used the injection of 1 cc. of paraldehyde for convulsions of prolonged duration which did not respond to other treatment and in cases of status epilepticus. In most instances the convulsions ceased promptly; in some the effect was neither prompt nor lasting, and even a repetition of the injection failed, on rare occasions, to have the desired result. The types of cases varied. Some attacks were generalized seizures which came in rapid succession in patients who were commonly regarded as epileptic. In such cases the effect of the paraldehyde was almost universally good. When definite organic disease of the brain could be demonstrated, for example tumor, subdural hematoma or dementia paralytica, the convulsions did not always cease with the injection of 1 cc. of the drug. A second injection sometimes succeeded after the first failed. More rarely the paraldehyde was altogether ineffective.

While the effect of paraldehyde in excitement and delirium, particularly of the alcoholic variety, is well known, its intravenous injection is not commonly utilized nor is adequate mention made of it in the literature. Sollmann's Pharmacology does not mention the intravenous use of paraldehyde at all and does not even mention convulsions. Cushny's Pharmacology fails to say a word about intravenous use, tells nothing about intravenous injections and does not refer to convulsions. The Textbook of Medical Treatment (Edinburgh, 1939), by various authors, advises paraldehyde by rectum or mouth for convulsions but does not mention the intravenous use. Bastedo's Materia Medica speaks of its use in eclampsia and other "convulsive conditions." He recommends one half ounce doses

by mouth. He adds that in "2 to 5 per cent solution in physiological saline it is also employed intravenously as a general anesthetic for short operations." It is evident that the intravenous injection of paraldehyde is not generally known, though I have used it for twenty years¹ and know of its use by others. This therapeutic procedure is not novel, but it seems to be startlingly so to the uninitiated.

This note is therefore made for the purpose of calling attention to a harmless therapeutic measure which in many instances is specifically effective when other drugs fail to stop convulsions. Repeated seizures always are terrifying to the beholder and frequently resist general medicinal attempts to control them. Status epilepticus, it is well known, may end fatally. The paraldehyde injection is so simple that it should be used in all cases of extremely prolonged or rapidly recurring convulsions. It is not indicated in the simple fit of comparatively brief duration. That generally ceases by itself and needs nothing to control it. The intravenous injection may be used with impunity in states of excitement and delirium with hyperkinesia and insomnia.

70 East Eighth-Third Street.

TETANUS: SECOND ATTACK WITH RECOVERY REPORT OF CASE AND REVIEW OF LITERATURE

HYMAN I. VENER, M.D., C.P.H., AND ALBERT G. BOWER, M.D.
LOS ANGELES

This is the report of a case in which a second attack of tetanus occurred approximately three and one-half years after a boy had been successfully treated and had completely recovered from one attack.

The method of management as instituted during the first attack has been described¹ and since 1935 has proved successful in 100 cases of tetanus, with a gross fatality rate of 29 per cent. If the deaths occurring within the first twenty-four hours after admission to the hospital are excluded, a net fatality rate of approximately 19 per cent has been achieved, one of the lowest in medical literature.

FIRST ADMISSION²

History.—J. Z., a Mexican boy aged 5 years, admitted to the communicable disease unit of the county hospital on Jan. 24, 1936, had been ill two days with inability to open his mouth, irritability and, on the least noise, a stiffness and jerking of the body, legs and back. The parents recalled hazily that the patient had stepped on a nail.

Physical Examination.—The rectal temperature was 98.8 F., the pulse rate 110 and the respiratory rate 24 per minute. Trismus, rigid neck, rigid abdomen, spasticity of all extremities, hyperactive reflexes and several infected lesions on the plantar surface of the right foot were found.

Laboratory Data.—Spinal puncture revealed a clear fluid under slightly increased pressure with a normal cell count and with sugar 52 mg. and chlorides 590 mg. per hundred cubic centimeters of fluid. Subsequent cultures taken of excised tissue from the infected lesions of the right foot yielded *Staphylococcus aureus* and *Bacillus coli* but no anaerobic organisms. Microscopic examination of the tissue revealed chronic inflammation and a point of perforation by a foreign body.

Treatment.—As outlined previously, in the first twenty-four hours of admission 160,000 units of tetanus antitoxin was administered. The dosage was distributed intramuscularly as follows: 20,000 units locally about the wound and 40,000 units encircling the right thigh, the latter procedure being repeated in eighteen hours. Cisternal puncture was done and 20,000 units admin-

istered about three hours after the initial intramuscular injection of serum. This produced a severe febrile reaction; therefore the intravenous injection of antitoxin was not given until twelve hours had elapsed, at which time 40,000 units of antitoxin diluted in physiologic solution of sodium chloride was used. Following the intravenous procedure a severe serum reaction ensued; consequently the usual second dose of 20,000 units intravenously was not given. Methenamine 15 grains (1 Gm.), 10 cc. of a 10 per cent solution, was given intravenously about ten hours after each intramuscular injection and two hours after the intravenous injection of antitoxin. Sedation for the control of spasms and convulsions was obtained as needed by chloral hydrate and calcium bromide by retention enemas. The lesion on the foot was completely eradicated and subsequently treated with hot potassium permanganate compresses until granulation and healing occurred.

Clinical Course.—Serum sickness developed on the sixth day but responded readily to treatment. The temperature became normal on the eighth day. The disappearance of trismus, rigid neck and rigid abdomen was slow and necessitated a longer stay in the hospital than usual. The patient was discharged from the hospital as cured on the thirty-first day.

SECOND ADMISSION³

History.—The same boy at approximately 9 years of age was readmitted to the service on July 5, 1939, with a history of drowsiness for five days, of pains in the chest, of restlessness, of having vomited and of having bitten his tongue repeatedly. His father observed the boy's drowsiness and when he attempted to arouse him the child would become restless, roll in bed, bite his tongue and return to his drowsy state. About a week previous to the illness, the patient had been struck on the right shoulder with a dirty stick, but about two weeks before that he had also cut his right foot on some glass. Following his discharge from the hospital about three and one-half years before, asthma had developed, particularly when the child was playing around horses.

Physical Examination.—The rectal temperature was 100 F., the pulse rate 92 and the respiratory rate 20 per minute. Marked trismus was present, the patient being able to open his mouth only one-fourth inch. The tongue was bleeding and showed evidence of repeated bites. There was marked risus sardonicus. The sternocleidomastoid muscles were tense and spastic. The neck, abdominal and back muscles were all very rigid. Moist musical rales were heard in the lungs, and hyperactive reflexes and frequent convulsions were present. Crusted, semihealed abrasions and lacerations were found about the right shoulder, the right middle finger and the right heel. The lesion on the heel was considered the most probable focus.

Laboratory Data.—Culture reports of excised tissues from the shoulder, finger and heel lesions were all negative for anaerobic organisms. Electrocardiograms one week after admission showed a sinus tachycardia and an inverted T in lead 4F, in keeping with the age of the patient. Examination during the second week disclosed a primary sinus arrhythmia and a premature ventricular contraction, as revealed by a left axis deviation, a polyphasic T in lead 4F and one premature contraction of ventricular origin. Roentgenograms taken of the dorsal vertebrae on dismissal showed no evidence of compression fracture.

Treatment.—Owing to the previous tetanus therapy, during which course serum sickness developed, followed later by the asthmatic attacks when around horses, and because of a current strongly positive cutaneous reaction to serum, the method of management was modified and he was given 100,000 units of antitoxin intramuscularly, administered as follows: 20,000 units about the right shoulder region, 10,000 units about the base of the right middle finger, 20,000 units about the lesion on the right heel and 50,000 units encircling the right thigh. An hour later, under a brief general anesthetic, all described lesions were completely eradicated, due caution being taken to stay within the zones injected. Ten hours later, methenamine 15 grains, 10 cc. of a 10 per cent solution, was given intravenously.

3. Supervised management of the case was conducted by Dr. Ralph Hanna, resident physician, and Dr. Lorin C. Swift, intern.

Sixteen hours after the first injection of serum another dose of 100,000 units of antitoxin was administered, divided and distributed as before and followed in ten hours by another intravenous injection of 15 grains of methenamine. Thus the patient received a total of 200,000 units of antitoxin, all intramuscularly, within eighteen hours after hospitalization. There were no untoward effects. Spasms and convulsions were controlled with chloral hydrate and sodium bromide by retention enemas as needed.

Clinical Course.—Convulsions persisted during the first twenty-four hours after admission. A profuse purulent nasal discharge associated with a secondary sinusitis and bronchitis occurred, which responded to nasal shrinkage and postural drainage. A severe serum sickness developed on the fifth day, resulting in increased irritability and spasms which persisted for four days but gradually responded to treatment. On the eighteenth day a hordeolum of the left eye and a generalized furunculosis developed, but both responded slowly to treatment.

On the thirty-first day of hospitalization the patient was discharged as cured, with instructions to return at stated intervals for injections of toxoid to afford some degree of future immunity.

REVIEW OF LITERATURE

A review of the literature discloses great confusion in the ability to distinguish between a relapse and a second attack of tetanus.

A relapse may perhaps be defined as a return of the initial signs and symptoms of tetanus following a relatively short period of complete cessation of symptoms, though the persisting infection or lesion may still be present. What constitutes a reasonable time interval between recurrence of symptoms is a debatable point, but it certainly should not exceed several weeks to a month.

When several months has elapsed with complete freedom from symptoms following the successful treatment of clinical tetanus, it seems fair to assume, in the presence of new causative factors, that one is dealing with a second attack of tetanus. All known foci or suspicious lesions must have been completely eradicated and the wounds present during the former attack completely healed.

However, in either case there may not be a history of recent trauma nor may one be able to detect the initial lesion.

Second attacks are reported by: Turanu,⁴ with an interval of fourteen months; Bérard and Lumière,⁵ who reported Péhu and Matelin's case, with an interval of five months; Palma⁶ with an interval of nine months; Speed,⁷ whose case was due to shrapnel, apparently overlooked at the time of the injury, with an interval of fourteen months, and, finally the Dumitrescos,⁸ with an interval of six months.

Relapses of convalescent and apparently recovered cases of tetanus may be cited in the cases reported by Fink,⁹ whose patient had two relapses within a period of six months, while under continuous medical supervision, and by Honda,¹⁰ whose patient, ten weeks after apparent cure (during which time he had received additional tetanus antitoxin), had a relapse and died.

COMMENT

Our case appears to be the sixth instance reported in the literature of a second attack of tetanus in the same patient. There may be others, and it would be of interest to have them reported.

SOME MEDICAL ASPECTS OF CHEMICAL WARFARE AGENTS

A REVIEW

LEON GOLDMAN, M.D.

AND

GLENN E. CULLEN, PH.D.

CINCINNATI

The greatest menace of poison gas is its fear inducing properties.

—F. N. Pickett.¹

Ever since the appearance of that huge ugly chlorine cloud in Flanders Field on April 22, 1915, chemical agents have proved themselves efficient warfare agents. Because of this simple fact and in spite of all signed political documents to the contrary, these materials will be used when necessary and when available in future warfare. Since the technic of modern warfare has changed so considerably the civilian and especially the civilian physician must have more than an academic interest and knowledge of chemical warfare compounds.

The official report² of the ninth International Congress of Military Medicine and Pharmacy includes the sentence "Considering the great progress of the chemical industry in all countries since the war, the new discoveries made in this field, and the technical advances in other methods of warfare, it is very likely that in future wars the use of gas will be made on a larger scale." Incendiary bombs and mustard gas were used extensively and efficiently in the Italo-Ethiopian War. So far, incendiary bombs and flame throwers, but not gas, are being used in the present European wars.

There have been too few voices raised to rid the public of this propaganda induced fear of chemical warfare. Notable of these voices has been J. B. S. Haldane³ with his "Callinicus: A Defence of Chemical Warfare." Others have been the chemist James Kendall⁴ with his "Breathe Freely" and, in this country, Prentiss⁵ with his technical work on "Chemicals in War." Frequently the noninformed physician shares in this unwarranted fear of chemical warfare. Since the last war there have been relatively few changes in the actual principles of the treatment of chemical warfare casualties, but there has been considerable progress in the study of the organization of the civilian aspects of this form of warfare. In recent years only scattered reports have appeared in the American medical literature.

In order to emphasize the clinical aspects of the lesions produced by the chemical warfare agents, we have included in our review only the more important principles. We have learned that otherwise the subject will appear too confusing and the practical aspects will be lost. The detailed study of specific portions can be investigated by the individual interested.⁶ This review

will consider the military aspects only as they are concerned directly.

Very early it was found that all the agents used at present could be classified, physiologically, into five groups: (1) lacrimators, (2) lung irritants, (3) vesicants, (4) sternutators, (5) nerve and blood poisons. This classification is essentially that of Julius Meyer.⁷ The Chemical Warfare Service of the United States during the last war examined some 4,000 substances, only fifty-four of which were tried in the field and only twelve in use at the end of the war. At the present time, and as far as can be determined, the efficient chemical warfare materials of England, France, Germany, Italy and the United States are practically the same. In the groups indicated the more important ones, from the point of producing casualties, are the lung irritants and the vesicants.

It is seen readily that quite a number of difficult situations arise with the problem of caring for the casualties of civilians and especially of large numbers of civilians. Previously trained personnel, both medical and nonmedical, is absolutely necessary. This is called "gas discipline." The number of gas casualties is always inversely proportional to the character of gas discipline. This has been realized in all European countries and for some years this form of training and preparedness has been going on.⁸

Physicians will be concerned with those casualties in which pulmonary damage and skin burns have been incurred. Sometimes in the midst of confusion and panic but little can be done, and yet, on the other hand, treatment must be instituted as early as possible to prevent serious reactions and death. It is seen from the table for the dangerous lung irritants that absolute rest is needed and, of course, rest in a gas free atmosphere. Any shelter that is free from the penetration by the noxious gases must have some method of producing or obtaining its own pure air supply, otherwise the "air tight" room will soon become uncomfortable and perhaps even dangerous, especially if it is crowded. So the patient must be brought by stretchers or ambulances to previously arranged treatment centers. Because of the insidious nature of these gases, it is much safer to consider any gassed patient as in a serious condition. Artificial respiration must not be given since the patient gassed by the pulmonary irritants must be kept at absolute rest. The most serious symptom to combat is, of course, pulmonary edema. Especially with phosgene, this may coexist with deep cyanosis and increased venous pressure (the so-called blue type of asphyxia) or with the even more serious form, the shock form (the so-called pallid or gray type). The treatment is, of course, different with each of these types. For the first type, oxygen of course should be given. If the various types of oxygen inhalation apparatuses are not available, oxygen may be given in a much less efficient manner by means of subcutaneous injections. Henschen⁸ reports that 500 cc. may be so given. Venesection also should be done, especially if the neck veins continue to be distended and the right side of the heart continues to be dilated. At the present time some are advising the prophylactic use of chemotherapy, such as the quinine derivatives and sulfapyridine, to prevent the

secondary bronchopneumonia. However, bronchopneumonia is not very common on recovery from the acute phase of phosgene poisoning and the bacteriology of the bronchopneumonia has not been studied thoroughly. Therefore the value of these drugs is not known at present. For the pallid type of asphyxia as much of

by the lung irritants is acute pulmonary edema associated with emphysema, and pulmonary vessel thromboses. The other significant visceral pathologic changes include purpura especially throughout the brain, and dilatation of the right side of the heart. When a patient gassed by a lung irritant also needs surgical attention,

*Some Clinical Aspects of the More Important Chemical Warfare Agents**

Group Agents	Physical State and Odor	Persistence	Significant Concentrations, Mg./L. or Oz./1,000 Cu. Ft. Exposure of 10 Minutes (Prentiss)			Symptoms	Treatment	Protection Against
			Lowest Irritant	Intoler- able	Lethal			
Lacrimators Chloracetophenone	Powder with a locust odor	Days (solid)	0.003	0.0045 (impossible to reach in field conditions)	0.85	Eyes water and burn; skin, especially freshly shaven, smart	Boric acid eye solution, sodium bicarbonate solution to skin	Gas mask
Brombenzyleyanide	Powder with sour fruit odor	Days (solid)	0.00015	0.0008	3.5	Watering of eyes; burning of nose	Boric acid solution	Gas mask
Lung irritants † Phosgene.....	Colorless gas, odor of moldy hay	Nonpersis- tent	0.005	0.20	0.50	Choking cough; insidious; blue or pallid types of asphyxia	Absolute rest; warmth; shock treatment; oxygen therapy methods; for pulmonary edema	Gas mask
Chloropierin (used in civil life as insecticide, fungicide, and to remove rats from ships)	Slightly oily colorless liquid; odor of fly paper	Nonpersis- tent (more so, however, than chlorine or phosgene)	0.009	0.050	2.00	Lacrimation and vomiting in weaker concentrations; definite lung irritation; may be insidious	Wash eyes with boric acid solution, otherwise, same treatment as for phosgene	Gas mask
Vesicants Mustard gas.....	Oily and colorless in pure state; later becoming brown; mustard or garlic odor	Persistent	0.001	Eyes 0.001 (1 hr.)	0.15	Delayed symptoms 2-6 hours from vapor burns, 15 minutes to 1 hour from liquid burns, blisters on skin and severe irritation of lungs if breathed in	If treatment delayed, skin burns cannot be prevented; wash with soap and water, gasoline, carbon tetrachloride, weak solution of bleach powder (irritant 1); late treatment that of burns in general	Gas mask protects only the lungs; special clothing
Lewisite.....	Colorless liquid; odor of geraniums	Persistent; slightly less than mustard gas	0.0008	0.0008	0.12	Sneezing; in 15-30 minutes skin burns; later arsenic poisoning	Immediate treatment, soap and water; ferric hydrate pastes and general measures	Gas mask; special clothing
Sternutators Diphenyl-chlorarsine (sneeze gas)	Dark brown liquid; odor of shoe polish	Nonpersis- tent	0.0005	0.0012	1.50	Coughing, sneezing, vomiting, headache and mental depression later	Rest; mouth wash of sodium bicarbonate solution and instil in nose also; early, breathe chlorine from bleaching powder bottle	Gas masks with excellent filters developed at present (if mask is defective, this gas will penetrate)
Diphenylamine chlorarsine (adamsite)	Solid; dark green or brownish tint yellow, almost odorless at ordinary concentrations	Nonpersis- tent	0.00038	0.005 (3 min.)	3.00	Same as foregoing	Same as foregoing	Same as foregoing
Nerve and blood poisons Hydrocyanic acid	When pure, a clear, colorless liquid with odor of bitter almond	Nonpersis- tent	0.020	0.030	0.200	Faintness, dizziness, dryness of throat, coma and death	Death too quickly for any therapy; may try artificial respiration, restoratives	Gas mask (special canister)
Carbon monoxide (produced by practically all explosives)	Colorless, odorless gas	Nonpersis- tent	0.7-0.8 ‡ (1 hour)	1.1-1.4 ‡ (1 hour)	4.6 ‡ (1 hour)	Blurring of vision, weakness, headache, coma, peculiar cherry tint, death	Remove to fresh air, artificial respiration, intravenous methylene blue (?)	Gas mask (special canister)

(Although hydrocyanic acid and carbon monoxide were tried in the last war, they in all probability will not be used now because of their too rapid dispersion.)

* Table modified from Prentiss, E. B. Vedder (Medical Aspects of Chemical Warfare); Sartori (The War Gases) and others.

† Chlorine is not included because chlorine is not used as such by any nation.

‡ Henderson and Haggard (Noxious Gases).

routine shock therapy should be given as is possible. In this condition the shock plus the emphysema, of varying degree and distribution (even mediastinal) may obscure the presence of moisture in the chest. In general, the treatment of this form is very discouraging and the patient may die within several hours in spite of intravenous injections of various forms of blood and other fluids, and cardiac and respiratory stimulants, even if all these materials are available in the emergency first aid stations. Briefly, the essential pathologic condition caused

he may be operated on when his general condition "warrants." Local anesthesia, nerve block of sacral or spinal type, are the forms preferred. Chloroform may be given.⁸

The other dangerous forms of gas poisoning are by means of blistering agents, the "chemical lepers." This phase has been reviewed in great detail for the dermatologist.⁵ Because of the persistence and efficiency of these agents, these will be used frequently in preference to the lung irritants. These gases too are insidious. For

some hours with mustard gas there is no complaint; then the eyes may become reddened and the skin burns and itches, especially in the moist sweating areas. Erythema appears chiefly in mild cases, in the form of a punctate eruption if the exposure has been slight. This may clear in from twenty-four to forty-eight hours. In severe cases the color may become darker, bullae are formed after eight to twelve hours and, if the patient has breathed in the gas, bronchopneumonia may occur. Occasionally pigmentation results from mustard gas burns even after mild degrees of erythema. This may last for several weeks and then the skin desquamates and the color fades. To prevent skin burns, the vesicant must be removed from the skin in from three to ten minutes. Under most situations and especially with uninformed patients this will be impossible. It is important for the physician to note that these patients are dangerous for him to handle. Unless the physician is protected properly against breathing the chemical agent vaporizing from any of these areas, he, the physician, will become a casualty. The gas mask will protect only against breathing the poison gas but will not protect the skin surface or the clothing. Special oilskin gloves and oilskin clothing are needed. With these cumbersome outfits it is difficult and impossible to work for any long periods. Liquid vesicant agents may be removed from the skin with soap and water, kerosene, gasoline or carbon tetrachloride. It must be remembered that these materials are only solvents and not neutralizing agents and therefore fresh cloths should be used each time. If bleaching powder solution is used to oxidize the gas, this solution of bleaching powder must be removed from the skin in order to avoid burning with this also. For burns with lewisite gas, a neutralizing agent such as 5 per cent solution of sodium hydroxide may be used and then rinsed thoroughly from the skin. After the bulla has formed, débridement should be done. Various pastes are then used, but it is doubtful whether they have any "specific" action. Tannic acid solution was used to treat mustard gas burns in the Italo-Ethiopian War and the results, uncontrolled, seemed encouraging. These cutaneous burns are relatively slow in healing and the patient's morale must be kept up during this period. Unlike the pulmonary complications following the lung irritants, bronchopneumonia is much more common after irritation of the tracheobronchial tree with mustard gas. For lewisite, the general measures to minimize the subsequent arsenical intoxication must be given. The usual bland treatments should be used on the eye injuries. It is recommended that no cocaine be used in the eye and that the eye be not bandaged. Briefly, the pathologic changes of mustard gas poisoning include, in the skin, perivascular infiltrates, vessel thromboses and vesicle and bulla formation. In the lung the picture is chiefly that of severe ulceration of the trachea, larynx and bronchi; bronchopneumonia and pulmonary abscesses may occur later.

Since mustard gas is persistent, lasting for days, weeks and even months under certain conditions, areas contaminated by this gas are dangerous for some time. These areas must be freed from mustard gas or decontaminated, as it is called. This is done usually with bleaching powder solutions and vigorous cleansing; contaminated clothing may be decontaminated by long exposure to windy air, by boiling, by chlorination or by the action of bleaching powder. As was mentioned before, special clothing must be worn, because this gas will penetrate cloth and even shoe leather. Because of

all this elaborate routine, it is seen readily that special treatment centers are required to treat mustard gas patients. Moreover, food and water supplies also can be contaminated. Severe poisoning can result from the ingestion of such materials. Water can be freed by the methods mentioned. Food usually must be discarded and destroyed. As a rule, intact cellophane wrappers or glass jars will protect food. Ordinary paper wrapping and paper bags do not protect. It should be emphasized again that early and prompt measures must be taken for patients affected by the lung irritants and blistering agents; in many instances even this purely symptomatic treatment will not be available.

BRIEF SUMMARY OF FIRST AID MATERIALS

From the data presented it is evident that there must be set up special treatment centers for the chemical warfare casualties. These patients cannot be handled adequately in an ordinary first aid station. In the treatment center, special rooms must be set aside for patients contaminated by mustard gas. Special precautions must be taken about the clothing of such patients. The general material required in the ideal protected treatment center would be (1) stretchers and beds, (2) blankets, (3) hot water bottles, (4) hot drinks, (5) fresh clothing, (6) oxygen breathing apparatus, (7) gastric tubes, (8) gas masks, (9) mustard gas resistant clothing, gloves, sheets, (10) venesection needles. The special materials required would be (1) bleaching powder, (2) sodium bicarbonate, (3) alcohol, (4) carbon tetrachloride, (5) kerosene, (6) soap and water, (7) 5 per cent sodium hydroxide, (8) ferric hydrate paste (value ?), (9) compound tannic acid solution,⁹ to be used for patients received with bullae already on the skin, (10) silver nitrate solution (10 per cent), (11) cocaine solutions, (12) morphine, (13) gentian violet (1 per cent), (14) heart stimulants, (15) respiratory stimulants (caffeine, xanthine derivatives), (16) fluids for intravenous use: (a) blood, (b) plasma, (c) dextrose, (d) acacia, (e) methylene blue, (f) sodium thiosulfate. As mentioned before, all cases should be considered as serious and so treated. For minimum therapy, a patient subjected to a lung irritant must be held at absolute rest and kept warm for some hours. For the patient exposed to mustard gas, the clothing must be removed, the body surfaces washed with soap and water or kerosene or bleaching powder or paste must be used. In times of stress, this really may be all that can be done. To keep a treatment center effective, patients should be removed as quickly as possible. They can be moved only by ambulance when that procedure is safe for the patient and the patient himself is not potentially dangerous to those who may care for him in the next treatment area (hospital).

THE GAS MASK

The ordinary gas mask consists essentially of some form of filter, contained in a metal box called the canister, and a tight fitting face mask. All air breathed in must come through the filter. The expired air is forced out through a valve. The filter is really a combination of mechanical filtering and of chemical reaction to adsorb and neutralize many of the gases. It is difficult to say just how long a mask will last. Apparently for the concentrations encountered in civilian life the mask

9. Fantus, Bernard, and Dyniewicz, H. A.: Compound Solution of Tannic Acid in the Treatment of Burns, *J. A. M. A.* 109: 200 (July 17) 1937.

may be good for many months (?). In general, the mask now in use will protect against the breathing in of all the present known war gases. The ordinary masks, however, will not protect against ammonia, hydrocyanic acid or carbon monoxide gases. For certain individuals a diaphragm may be incorporated in the face piece of the mask so that one can speak with the mask on. If one wears glasses constantly it is difficult to wear those with the ordinary mask. For the eye pieces of the mask, materials are provided to protect against clouding over with moisture. When the proportion of oxygen in the air is low, below 16 per cent, the gas mask will be of no use. Under these circumstances the person must carry, attached to his mask, his own oxygen tank, and the whole intake system will be a closed one. A mask with a hose reaching out into pure air can also be used. The gas masks for infants must of necessity be really a complete tent arrangement. Animals also must have some sort of mask.

Of course, the mask reduces to some extent the efficiency of the individual wearing it. When the wearer becomes accustomed to the mask and loses his fear, he can do his ordinary work with ease. It is difficult, however, to do fine and close work with the mask.

SPECIAL SITUATIONS AND REQUIREMENTS

It is obvious that the use of chemical agents for warfare against civilians suggests many additional problems. Only a few of these will be considered here. It has been mentioned before that a person affected by blistering gases may have also wounds requiring surgical treatment. This patient is dangerous to care for until, at least, his clothing is removed and his skin treated. There is also another angle to this, namely special precautions in the operating room under the potential danger of bombing with war gases. If the patient is getting general anesthesia, this anesthesia must go through a special mask. The surgeon and first assistant should have masks. Some recommend that, if there is any possibility that the air in the shelter may go below the desired oxygen levels, these two important members of the surgical teams be provided in advance with oxygen masks. All others in the room must also wear masks. For mustard gas, special clothing is needed in addition. If possible, extra personnel should be in the room to take care of decontamination so that the surgeon and the patient need not be disturbed. To avoid this complicated set up, operating rooms in the city should be bomb proof and have independent air purification.

The medical care of chemical warfare casualties produced on board ship is even more complicated. There is usually no good place to evacuate casualties. The ventilating system must be watched carefully; otherwise the gases may be drawn throughout the ship. Mustard gas may remain on the painted surface for some time and then, when warmed, vaporize and cause burns. Food cargoes carried by the ship may be contaminated also. It has been suggested that ships gassed, especially with mustard gas, be marked with special quarantine flags.

Agents for chemical warfare are dangerous to manufacture. The workers must be protected against the industrial hazards, chiefly various forms of cutaneous irritations and burns. Cleanliness in the factory and training of the worker (gas discipline) will do much to reduce these hazards.

INCENDIARY AGENTS

Of great importance to civilian population is the use of "thermite" bombs. Thermite is an intimate mixture of iron oxide and finely powdered aluminum. With a suitable starter, at high temperature, the aluminum and iron oxide react to form aluminum oxide and molten iron. There is also the kilo magnesium (electron) bomb¹⁰ with a primary composition of the thermite type and the tube of an alloy of magnesium with a small proportion of aluminum. In this bomb everything, including the tube, is incendiary material. When bits of these materials come in contact with the body, very severe deep burns are produced. As one might imagine, burns even from tiny particles are very painful. The treatment is the usual treatment for severe metal burns. Such burns are said to cause more fear and panic than burns from the vesicants.

Phosphorus burns may also be encountered when this chemical is used to produce concealing smokes. These burns are treated by keeping them protected from all air by means of water or oil, or by using copper solutions to form insoluble salts. Combustible oils mixed with soap or jelly and containing small pieces of metallic sodium may also be used as incendiary agents.

RESIDUAL EFFECTS OF CHEMICAL WARFARE AGENTS

There is a vast amount of misinformation on the residual effects of chemical warfare agents. The blame for practically every complaint, respiratory or otherwise, in veterans has been placed on "being gassed in the war." The truth of the matter is that there are relatively few residuals from chemical warfare and certainly not those horrible ones following shrapnel, gunshot wounds and the like. If any kind of warfare could be called "humane," chemical warfare warrants such a term. The question of the future of chemical warfare casualties has been studied thoroughly by Gilchrist and Matz.¹¹ In most instances "gas discipline" was very poor and many casualties were suffered through carelessness. Moreover, with little if any immediate therapy in most cases the relatively low percentage of sequelae is indeed surprising. With an efficient arrangement with trained personnel, this percentage could be reduced even more.

THE DETECTION OF CHEMICAL WARFARE AGENTS

The most reliable method at present to detect these compounds is through their odor. This, of course, presupposes a knowledge of the characteristic odors of these gases. Such knowledge can be obtained by repeated training. This is done usually by smelling small quantities of these materials adsorbed on particles of charcoal and contained in a glass bottle. It is important that the odor be recognized with the first cautious sniff, since repeated smelling dulls the olfactory sense and may even be dangerous. A trained observer is said to be able to identify the agent by other immediate effects on the body such as irritation of the eyes, nose and throat and pricking of the skin. Prentiss⁴ stresses the fact that one should be able to distinguish gas from powder fumes. With the ignorant untrained civilian there is only the memory of what he has read or heard and, later, what he has experienced.

There is no simple, easy, specific chemical method to detect the presence of these war gases. Gigon and

10. Air Raid Precautions Handbook No. 9: Incendiary Bombs and Fire Precautions, London, His Majesty's Stationery Office, 1939, p. 1.

11. Gilchrist, H. L., and Matz, Philip B.: The Residual Effect of War Gases, Washington, U. S. Govt. Printing Office, 1933.

Noverraz¹² have described a colorimetric quantitative method depending on the hydrolysis of the gas with the formation of acids. They state that the determinations can be made very quickly.

SUBJECTS NOT INCLUDED

Since this review is to be practical and clinical, many subjects have been omitted. Some of these are of great importance, such as the medical aspects of individual protection in the home, the detailed setup of mass protection facilities, the elaboration of "fear psychology" of gas masks and chemical warfare, the applications of methods of chemical warfare to insect destruction and the like, review of some of the work on the hydrolysis of the war gases, and the chlorination of mustard gas (and lewisite). There has been left out a discussion of some of the less common gases such as ethyldichlorarsine, phenyldibromarsine, ethyldibromarsine, perstoff (trichlormethyl chloroformate), cyanogen chloride, and those chemicals which produce screening smokes such as titanium tetrachloride, sulfur trioxide and oils. Nothing is known at present about the administration of sulfanilamide or its related compounds in gas poisoning in order to prevent subsequent wound infection or for the actual therapeutics of infections associated with the gas poisoning. The subject of complete destruction of cities by poison gas is not even considered, since this is entirely impossible now and is merely a myth produced by imaginative writers. There is always the real danger of the production of new and powerful gases which will not fall into our present categories. This is not an easy task because the gas must have the following properties:

1. The gas must have a definite toxic quality (or produce smoke or incendiary activity).
2. The raw materials must be available.
3. The gas must be noncorrosive on storing.
4. The gas must be stable.
5. The gas must be heavier than air.
6. The gas should be susceptible of being liquefied.

The chemical warfare industry is closely associated with the dye industry. From our medical point of view we can always give symptomatic treatment. Our ideal, however, should be causal therapy. Our Chemical Warfare Service¹³ adds that "no agent is known which is more effective than mustard gas in sending men to the hospital; and there is little evidence that a gas more effective than phosgene is available for poisoning the air."

SUMMARY

This review is not intended to be an encyclopedic reference work on chemical warfare. It merely emphasizes some of the more important points of the medical aspects of such warfare especially as it relates to the civilian physician. We must face the fact that such warfare is efficient and may be used. In fact, it seems much less dangerous as regards fatalities and residuals than the other commoner and more horrible forms of warfare. This brief report will provide a vocabulary for a type of medicine which is new to most of us, a type of medicine which will interest every branch of experimental and clinical medicine. With knowledge in advance we can assist in driving away the fear of the unknown. We can then reduce the number of casualties from these chemical compounds.

COMMUNITY OF INTEREST BETWEEN FEDERAL TRADE COMMISSION AND MEDICAL PROFESSION

K. E. MILLER, M.D.

Medical Director, United States Public Health Service; Director of the Medical Advisory Division of the Federal Trade Commission

WASHINGTON, D. C.

Professor Quiz would probably get some interesting answers from physicians as to what the FTC is and how it functions. That it is a member of the New Deal alphabetical family might be a good guess, but this would only get one the gong, as we shall later see. Even though we should give out the clue that the FTC is not a new governmental agency but one which has been in active operation for a quarter of a century, there would perhaps still be few who have a clear conception of the functions of the FTC which are of interest to physicians. It is for this reason that some explanations are believed to be not only appropriate but necessary for the information of the American medical profession.

At the risk of offending the intelligence of some of the better informed readers of *THE JOURNAL*, this explanation will be made quite elementary. It will be noted first that the fundamental principle on which the duties of the FTC rest is the elimination of "unfair methods of competition in commerce, and unfair or deceptive acts or practices in commerce."

Among the unfair trade practices with which the FTC has to deal, false and misleading advertising is one of the foremost problems. Of all the appeals made for popular attention, those pertaining to health and beauty aids are most voluminous. In the hope of securing these precious treasures, mankind will make any sacrifice of money and effort. The lure becomes all the more irresistible when offered at bargain prices as a short cut to the desired goal. In the keen competition for business, therefore, there is great temptation for vendors of foods, drugs, cosmetics and health devices to paint the pictures of their products in too rosy a light.

TRUTH IN ADVERTISING

It is perhaps rather generally understood that the Food and Drug Administration of the Department of Agriculture has something to do with the regulation of this group of products. It may not be so generally known, however, that the FTC also has obligations in this field. In order to dispel any confusion that may exist in this connection, it will be observed that the Food and Drug Administration exercises supervision over misbranding (labeling) and adulteration, while the FTC is charged with the duty of confining advertisers of these products to fair and truthful representations. This is strongly reminiscent of the trend of medicine from its earliest beginnings. Although no one would presume to say that medicine at any stage of its history has ever been free from fallacies, it has always been a champion of truth against falsehood in medical teaching and practice. While many of the medical axioms of a century ago would today represent the trappings of quackery, medicine has always been motivated by a sincere purpose to expose falsehood and espouse truth in accordance with the best standards of any given period. It should therefore be welcome news to the medical profession that its age old struggle for truthfulness with respect to drugs and similar products is now further fortified by the regulatory authority of the federal government.

For a clearer understanding of the way in which the FTC fits into this picture, a brief reference to the legal background will be helpful. The procedure in the interest of eliminating false advertising has not always been so simple and direct as it is at the present time. Prior to 1938 it was necessary, in addition to showing that the advertising actually was false and misleading, to establish the fact that such false advertising was detrimental to the interests of competitors and that in correcting the offending advertising the public interest would be served. These were the essential elements held by the Supreme Court to be necessary in order to establish jurisdiction under section 5 of the act of 1914, which declared "unfair methods of competition in commerce" to be illegal. Under this provision the major emphasis was placed on the protection of one competitor against unfair practices of another. It was obvious that the consumer's interest required more specific safeguarding. In order to accomplish this and otherwise to extend and simplify the legal procedure, the Wheeler-Lea amendment was enacted in 1938. Section 5 was amended by adding to the phrase "unfair methods of competition in commerce" the words "or unfair or deceptive acts or practices in commerce." This serves to give specific recognition to the Commission's duty to protect the public directly by the prevention of all unfair or deceptive acts or practices in commerce, as well as indirectly through the public's interest in the preservation of fair competition.

In addition to amending section 5, the Wheeler-Lea amendment appends several new sections (12 to 18 inclusive), giving the Commission further specific powers over the advertising of foods, drugs, cosmetics and devices. First of all, false advertising is defined in the following manner:

SEC. 15(a) The term "false advertisement" means an advertisement, other than labeling, which is misleading in a material respect; and in determining whether any advertisement is misleading, there shall be taken into account (among other things) not only representations made or suggested by statement, word, design, device, sound, or any combination thereof, but also the extent to which the advertisement fails to reveal facts material in the light of such representations or material with respect to consequences which may result from the use of the commodity to which the advertisement relates under the conditions prescribed in said advertisement, or under such conditions as are customary or usual. . . .

Any false statement, either direct or implied, by whatever advertising medium, comes within the foregoing definition. But it should also be observed that failure to reveal material facts is likewise classed as false and misleading advertising.

POWERS OF THE FEDERAL TRADE COMMISSION

Of special interest is section 13(a), which authorizes the Commission to apply for injunction under certain specified circumstances, whenever the Commission has reason to believe that such action "would be to the interest of the public." On securing a temporary injunction against the advertising of a product, all claims complained of in the injunction are ordered to be suspended "until such complaint is dismissed by the Commission or set aside by the court of review, or the order of the Commission to cease and desist made thereon has become final within the meaning of section 5." Already the injunction provisions have been invoked in a number of cases involving dangerous drugs. In no instance has an application for injunction been denied. Notable in this group of products

are numerous abortifacient remedies containing a familiar coterie of drugs—ergot, ergotin, apiol, oil of savin, cotton root bark, oil of tansy, quinine and various purgatives, among which aloes, cascara and podophyllin predominate. Another important group of preparations against which injunctions have been secured is the fat-reducing remedies. The lure of fat reduction is held out to overplump females by many and devious methods ranging all the way from hokus-pokus to toxic and dangerous drugs, including thyroid substance and the dinitro compounds dinitrophenol and dinitrocresol. Even the credulous soul who falls victim to some crackbrain theory will receive protection through the suppression of false advertising, but the injunction is reserved for the immediately dangerous products such as indicated.

The last sentence of section 15(a) was drafted with particular reference to the medical profession. This sentence reads as follows:

No advertisement of a drug shall be deemed to be false if it is disseminated only to members of the medical profession, contains no false representation of a material fact, and includes, or is accompanied in each instance by truthful disclosure of, the formula showing quantitatively each ingredient of such drug.

Some doctors have been under the impression that products advertised only to the medical profession are exempted from the requirements of the FTC. This conception is erroneous. It is assumed in the wording of the act that if a physician knows the formula for a preparation he is in a position to judge for himself as to the truth or falsity of the advertising representations relative thereto. It is, however, required that the advertising shall contain "no false representation of a material fact." Falsehood here, as elsewhere, may stem not only from what is said of a product but also from "material facts" which are withheld when such facts are necessary for the proper appraisal of a product.

One more item should be made clear before passing on from the legal considerations. The FTC cannot stop the sale of any product because of false advertising, nor is it endowed with authority to impose punitive penalties. Its maximum corrective power in such circumstances is the issuance of a cease and desist order specifying claims and inferences in advertising which are adjudged to be false and misleading after weighing all the evidence bearing on the subject. The cease and desist order also demands the discontinuance of the specific claims "or others of like import." While the law provides formidable civil penalties for violation of a cease and desist order, and criminal penalties including both fine and imprisonment for false advertising of commodities injurious to health, the prosecution leading to the imposition of these penalties is conducted by the Department of Justice rather than the FTC.

Since a discussion of legal matters is not destined to evoke an outburst of enthusiasm among physicians, I have endeavored to comment on the original act and the Wheeler-Lea amendment only enough to bear out the fact that the present law with respect to false advertising of foods, drugs, cosmetics and devices is reasonably adequate to deal with most of the abuses in this field. It is reasonable to suppose that the physician's major interest lies in the application of this law to matters which more or less concern him.

From what has already been said there could hardly be any mistake as to the type of advertising against which this discussion is directed. This is distinctly not an attack on advertising in general. There is good advertising and bad advertising. The former has a vital

and necessary part to play in our economic life and welfare. The latter is an outlaw against which the hand of the law and the bans of decency are raised. It is gratifying to note that there is an ever increasing urge from within the drug industry itself for more conservative and reliable advertising. It is being recognized not only as good ethics but also as good business. Any honest advertising, whether directed to the medical profession or to the lay public, may be assured of no difficulties at the hands of the Federal Trade Commission. On the other hand, false and fraudulent advertising may expect no quarter. No fair-minded advertiser could find fault with this policy. On the contrary, those who strive to tell the truth about their wares naturally applaud any measures designed to force their less scrupulous competitors to do likewise.

USE OF PROPRIETARIES

Preparations which are "factory made" from fixed formulas are called proprietary remedies. Perhaps the average physician would consider it beneath his professional dignity to discuss them. But in no small measure the medical profession itself has fallen into the habit of prescribing proprietary medicines. The art of prescription writing in its elemental form is on the road to oblivion. Prescriptions rarely contain specifications as to component drugs and quantities of each. The prescription will commonly specify some combination of drugs designated by a trade name because some detail man or the manufacturer's literature received with the sample has convinced the physician that the preparation is good for certain symptoms or ailments. He may know next to nothing about the actual contents of the product, and even less about their individual and collective therapeutic action. His knowledge of the therapeutic uses and limitations of ready-made products is all too often confined to such information as the manufacturer sees fit to give. In many instances the physician is quite as easily led astray by false advertising as is the layman. More will be said on this subject later in connection with testimonials.

While this may be a somewhat overdrawn picture, where is the doctor who doesn't at any time resort to ready-made drugs and mixtures bearing meaningless trade names? If these things be true, it hardly becomes the medical profession to look with scorn on proprietary preparations as such. There is, of course, little excuse for physicians prescribing proprietary medicines blindly, as they have at their disposal the advice of the Council on Pharmacy and Chemistry of the American Medical Association for their guidance. However, either through disregard of available advice or otherwise, many doctors do persist in taking their instruction in modern drug therapy from commercial houses. Since this is so, it should be gratifying to know that there is an agency which is authorized and able to require the drug distributors to tell the whole truth and nothing but the truth about their products.

DRUGS FOR SELF MEDICATION

The great bulk of the FTC's problems with respect to drugs, however, has to do with preparations sold to the lay public for self medication. This being the case, some may ask Why bring that up in a physician's magazine, since physicians as a rule are constitutionally opposed to self medication? Let us look at this issue in an unimpassioned and matter of fact light. Whether we like it or not, self medication is the inalienable right of Americans, and it is here to stay. Physicians cannot disclaim any interest in the matter, if for no other reason

than that too much self medication is detrimental to their professional interests. Another more laudable motive for looking into this matter with a searching eye is the fact that medical men are committed to the task of protecting health and life by whatever means, to the fullest extent of their ability. It is for this reason that for many years the columns of the American Medical Association have been thundering away at quackery and nostrums that prey on the lives and financial resources of credulous millions. A splendid contribution has thus been made, but the full fruition of these efforts rests with regulatory measures whereby compliance with certain standards can be enforced.

IMPLICATIONS OF SELF MEDICATION

Self medication then, like the poor, we shall have with us always. The question confronting the medical profession is what attitude we shall take toward the problem. The natural impulse is to turn a deaf ear. But sincere medical men cannot so easily dodge responsibilities. In fairness to mankind we must first inquire into the evils, if any, that arise from self medication and, having discovered them, address ourselves to the task of minimizing these evils as much as possible.

I will not attempt either to justify or to condemn self medication. There are perhaps extremists on both sides of this question. Rarely do any of the ill effects of improper medication, even by physicians, ever appear under their proper labels, either in the morbidity or in the mortality reports. Undoubtedly many lives have been saved and much unnecessary suffering relieved by resorting to home remedies. On the other hand, every physician in active practice has very likely had experience with mistakes of self medication. "Too late" it may be when the patient seeks the physician's care. Or, if not too late, the doctor's task is often immeasurably increased because of costly delays and other forms of damage wrought by a misguided faith in "home remedies." It is ordinarily left to the doctor to take over after self treatment has been tried and found wanting, which may mean either an attempt to repair any damage which may have occurred or the signing of a death certificate. The physician no doubt feels that he has enough of his own mistakes to bury without assuming this duty for others.

Certainly the hazards would be much less if along with a conservative recital of the virtues that might be anticipated the purchasers of home remedies were told the unvarnished truth as to their therapeutic limitations. If persons are going to buy medicines for self administration, as is inevitable, then in the interests of life saving, to which all upright physicians must be committed, they should be served with reliable information on which to base mature judgment. This having been done, the individual becomes solely responsible for any evil consequences.

THE FEDERAL TRADE COMMISSION AND THE PHYSICIAN

The FTC has undertaken to enforce truthfulness in advertising of drugs and allied products in order to safeguard the public, as far as possible, against physical disasters born of false and misleading claims. In this connection the physician may be either an indispensable bulwark or a pernicious obstacle. Doctors indeed furnish strange paradoxes. Incredible as it may seem, the files of the FTC are replete with letters and other data from physicians attesting the virtues of all grades and shades of proprietary remedies. It is safe to say that there is no nostrum so rank as to be unable to

secure endorsement by some one authorized to affix an M.D. to his name. Medical endorsement of this character is the source of no great annoyance, as its scientific value can be readily challenged. A much more serious embarrassment arises from medical authorities whose published statements are either too old or too new. In the former classification are many erroneous conceptions that have been carried forward from medical antiquity and incorporated into recently published textbooks. At the other extreme are the new and unproved ideas of recognized leaders in contemporary medicine. Though an idea may be nothing more than a vague theory or hypothesis, it at once becomes legal tender provided it emanates from some one whose name "packs a wallop."

There is, happily, another side of the picture which much more truly characterizes the medical profession. Those who unwittingly or otherwise hinder progress represent a negligible minority. The true spirit of the medical profession is portrayed in that class of men who have on numerous occasions given unsparingly of their time and talent to render medical testimony, without compensation, when called on to do so by the FTC. Among these unsung heroes are not a few who have been known to refuse fancy fees for testimony contrary to their convictions, preferring instead to testify for the government along the lines which they knew to be scientifically honest. The FTC is proud to acknowledge the valiant support it has unfailingly received from the medical profession in the investigation of its most difficult and important cases.

In July 1939 an appeal was made to the secretaries of the state medical societies for assistance in securing medical witnesses if and when cases requiring this service were to be heard within their respective jurisdictions. The response was uniformly prompt and generous in spite of the fact that it was explained that the FTC is without funds with which to pay expert witness fees. It is generally realized, I believe, by any one who gives the matter a second thought, that the work of the FTC in attacking false and misleading drug advertising is a complement to the efforts of the profession itself in this field. The parallel activities of the medical profession and the FTC, therefore, may be properly regarded in the light of mutual assistance. Although a large proportion of the medical cases handled by the FTC are settled by voluntary agreement or stipulation, the Commission must be prepared in every single case to substantiate its complaints by competent medical testimony. It may therefore be truly said that medical testimony, either actual or potential, is the very backbone of every single case in this category. When falsehood and innuendo in this class of advertising become too distasteful to the physician he may take consolation in the thought that there is a way out of this wilderness, but he must at the same time realize that he or his kind will not only have to assist in blazing the trail but also lend a hand to the spade work.

Early Outbreaks of Bubonic Plague.—Plague can be traced back almost uninterruptedly to the third century before the Christian era, when Dionysius told of it as a fatal disease in Libya, Egypt and Syria, and Homer's story would carry us some 900 years farther back. There can be no doubt that the epidemic in Libya described at the beginning of the Christian era by Dioscorides, a Greek surgeon to the army in the time of Nero, and Poseidon, a physician of Alexandria, was true bubonic plague.—Scott, H. Harold: *A History of Tropical Medicine*, Baltimore, Williams & Wilkins Company, 1939.

CONFERENCES ON THERAPY

TREATMENT OF BLOOD DISORDERS

I. IRON THERAPY

NOTE.—These are actual reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with the collaboration of other departments. The questions and discussions involve participation by members of the staff of the college and hospital, students and visitors. The next report will concern "Treatment of Blood Disorders: II. The Use of Iron and Other Metals."

DR. EUGENE F. DU BOIS: The conference today is the first of a series on the treatment of blood disorders. We hope that the plan of pursuing through several sessions a topic of limited scope will result in a more comprehensive discussion of the subject and perhaps also permit more time for informal discussion. We begin with iron therapy, and Dr. Warren will discuss the metabolism of iron with special reference to the red blood cells and hemoglobin.

THE METABOLISM OF IRON

DR. CHARLES O. WARREN JR.: We shall start by recalling the structure of the hemoglobin molecule, which, as you will remember, is made up of a "heme" part consisting of four substituted pyrrol groups and an atom of iron all linked together and combined with the protein globin. Apparently the body can synthesize the hemoglobin molecule from groups even simpler than the pyrrol nuclei, but under any ordinary conditions there is no lack either of these or of the constituents necessary for the synthesis of globin. Iron is more commonly the part of the molecule which is not present in adequate amounts in the diet, and we are concerned here with obtaining an understanding of the precise circumstances under which such a deficiency may arise. This should not imply that the body needs iron only for hemoglobin formation, for this element is an essential component of certain respiratory enzymes and other biologically active substances as well; but of the total iron in the body such a small amount is present in these forms that we can safely limit our discussion to the iron requirements of the body for hemoglobin formation.

I shall now merely enumerate some of the important points with respect to iron metabolism:

Iron is absorbed largely in the upper part of the small intestine. It is excreted almost entirely in the feces, though there is a very small loss in the urine. The iron in the stools represents that which has not been absorbed plus a fraction which may have been excreted into the intestine. The size of this latter fraction, and indeed its very existence, is by no means definitely established. It is clear however that, if normal males are kept for long periods of time on diets that contain very little iron, they excrete minimal amounts and appear to establish a balance between iron intake and excretion. The loss of iron from the body of normal males (but not females, as we shall see) as the result of endogenous metabolism is accordingly very small indeed and is covered by diets which are unusually low in iron.

Iron in any form is utilized for hemoglobin synthesis. The most complete studies indicate that, when there is a demand for hemoglobin, injected iron is utilized nearly completely for its synthesis. Even hemoglobin

itself, if given parenterally, is utilized almost quantitatively, but if given by mouth very much larger amounts are necessary, it is so poorly absorbed.

Despite evidence to the contrary in the case of the dog and the rat, I think the evidence is good that in man ferrous salts are absorbed more readily than ferric salts or iron in any other form. This has been a source of considerable confusion. There appears to be no special virtue in organic combinations of iron in the diet.

Gastric acidity favors the preservation and even the formation of ferrous ions and also prevents the formation of insoluble iron compounds, particularly ferric phosphate. The importance of free hydrochloric acid in the stomach from the practical standpoint is questionable, however. Cases of hypochromic anemia associated with achlorhydria are not cured more readily as a rule by giving hydrochloric acid with the meals.

Iron is apparently transported in the plasma. This is a very small part of the total iron in the blood, and it represents a labile form of iron. It is comparable in iron metabolism to the blood sugar in carbohydrate metabolism; for example, on a high iron intake plasma iron will increase, and during active erythropoiesis, as

Iron requirement of human beings (Heath and Patek).

in recovery from pernicious anemia, the plasma iron will be lowered as it is withdrawn from the blood for hemoglobin synthesis.

Whether iron is utilizable for erythropoiesis by bone marrow in the form in which it is absorbed or whether the initial stages of hemoglobin synthesis occur in the liver is not known with certainty, although the latter view is generally held. Iron is not regarded as a bone marrow "stimulant."

The total iron content of the body is of the order of 4.5 Gm. Of this, the circulating hemoglobin contains somewhat less than 65 per cent; "latent iron" available for hemoglobin formation and stored principally in the liver, bone marrow and spleen comprises about 30 per cent, and tissue iron, which is unavailable for hemoglobin formation, about 5 per cent. The fact that of the total iron in the body about 65 per cent is circulating in the blood and that about half as much is available to supply more hemoglobin if necessary checks with the clinical experience that a patient can lose about half the circulating hemoglobin and replace it from the reserves without the necessity for iron administration.

The iron requirement of an individual depends primarily on two factors, age and sex, and because of this I think it is important to diagram the requirements for the different ages and sexes in man. The chart shown is reprinted from a review article by Heath and

Patek in *Medicine*. The requirements have been calculated from data and assumptions stated in the original text.

The ordinate represents the annual iron requirement in grams, the abscissa the age in years. In infancy, after the first few months of life, the amount of iron that has to be added to the body decreases because growth is less rapid than initially, and at the age of about 4 years it reaches a steady level. This level means not that there is no additional requirement for iron but that the requirement is relatively constant at about 100 mg. a year. In adolescence the growth rate increases very rapidly, and during that period there is a large increase in the amount of iron that is necessary. With men, who reach adult size, we may assume, at about 21, the requirement then approximates zero since they lose so little of the iron which has already been absorbed into the body. This applies to normal men.

With women, on the other hand, the menstrual losses beginning in adolescence increase the requirement as compared with that of men. About 20 mg. of iron is required for each menstrual period, which represents the amount of iron lost in the blood of the menstrual flow. Growth falls off naturally, but the iron requirement owing to menstruation persists at the level of about 300 mg. a year until, say, the age of 45 years, when it too will decrease nearly to zero. Each pregnancy will constitute a special demand on iron metabolism which is only partially compensated by the amenorrhea, and a rise in the curve to nearly 400 mg. a year may be expected.

One can see from this chart at what ages one may expect to find iron deficiency anemias, namely during adolescence, when the chlorosis type of anemia used to be seen frequently, and in women of the age group from 20 to 45 years, particularly if numerous pregnancies have drained their stores of iron.

DR. DU BOIS: We could have a few questions at this point.

DR. PAUL REZNIKOFF: How does iron act? Why is it necessary in the body?

DR. WARREN: It is necessary in largest amounts as an integral part of the hemoglobin molecule, and it is its presence in the molecule that confers on hemoglobin the ability to transport oxygen. Hemoglobin iron is in the ferrous form, both in reduced and in oxygenated hemoglobin; the transportation of oxygen is therefore not associated with valence changes in the iron atoms. Much smaller amounts of iron are present in muscle hemoglobin and in the hemin respiratory catalysts, of which cytochrome is an example, but its action in the latter substances depends on its ability to be alternately oxidized and reduced—to alternate reversibly between the ferrous and ferric forms. A large part of the total oxygen consumption (cellular respiration) of most body cells depends on this catalytic action of iron. In view of its importance in the cell economy, it is not surprising to learn that iron in this form is retained in the cells even when there is an excessive demand for hemoglobin iron. The same is true of muscle hemoglobin.

DR. EPHRAIM SHORR: Does infection do anything to iron metabolism?

DR. WARREN: It has been found that cases of iron deficiency anemia do not respond well to iron therapy during a coexisting infection. This poor response is ordinarily interpreted as due to a "toxic" condition of

the bone marrow, but in order to establish this it would be necessary to show that iron absorption is not affected by the infection, and so far as I know such studies have not been made.

DR. SHORR: What do you mean when you say that the iron requirement in the adult male approximates zero?

DR. WARREN: Theoretically, if there were no iron loss there would be no need for iron in the diet. Actually, there is a very small but continuous loss of iron in the urine and there may also be a small excretion into the intestine. But these losses are apparently made up even with diets designed to contain as little iron as possible.

DR. DU BOIS: But that will not even let you cut your finger, will it?

DR. WARREN: That is true, and a good sized nose-bleed would constitute a real setback.

DR. WALTER MODELL: If a man does not excrete any iron after the age of 25, what happens to all the iron he ingests in his diet?

DR. WARREN: After he has built up his reserve supply of iron he comes into iron balance. He excretes an amount equivalent to that which he ingests.

DR. DU BOIS: Have you in your head the approximate figure as to how many pregnancies a woman could have on an iron deficient diet without exhausting her reserves of iron?

DR. WARREN: Heath and Patek give 375 mg. as an approximate figure representing the iron requirement for a pregnancy. Taking 1.3 Gm. as the reserve iron in the body available for hemoglobin formation, this would be pretty well exhausted by three or four pregnancies if none was absorbed from the diet during this time.

DR. McKEEN CATTELL: Is there definite evidence that those iron reserves are drawn on when there is need in relation to the hemoglobin supply?

DR. WARREN: Yes, as I say, it is common experience that patients can lose practically half the hemoglobin in the blood and then restore their blood hemoglobin level on an ordinary diet without the addition of iron.

DR. HARRY GOLD: There is also the fact that iron is of no value in acute hemorrhage but is of value in chronic hemorrhage, when the reserves are presumably exhausted.

DR. CATTELL: Is there no way of getting at the level of those reserves in the patient? The information would be useful as an indication of the existing factor of safety in relation to the likelihood of anemia developing.

DR. WARREN: There is no practical way for patients.

DR. REZNIKOFF: That work has been done on animals; the organs have been analyzed under various conditions of iron depletion, and it has been definitely shown that iron stores are drawn on to replace the acute hemoglobin loss in hemorrhage.

DR. GOLD: Do I understand rightly that iron deficiency anemia does not result in a man when his diet is free of iron?

DR. WARREN: It has not been practical to test this point directly by placing individuals for prolonged periods on diets that are entirely free of iron, except in starvation experiments. In these cases there is a

negative iron balance but this is interpreted as due to the breakdown of tissue cells. Certainly it is true that "idiopathic hypochromic anemia" is a disease of women and that men with hypochromic anemia are almost invariably found, on careful history and examination, to be suffering from some condition other than a mere insufficiency of iron in the diet. At any rate, the statement occurs in the literature that iron deficiency anemia cannot be produced in the normal adult who has no blood loss whatever.

DR. WILLIAM H. SUMMERSON: That, of course, is open to a good deal of experimental criticism.

DR. DU BOIS: I wonder if you would care to discuss that further.

DR. SUMMERSON: I have made some calculations from the chart Dr. Warren has shown, in which the iron requirement drops down to zero. That would be based, of course, on a study of iron intake. If a human being is put on a milk diet I think most people would admit he is under the condition of absolute minimum iron intake with otherwise adequate amounts of the various components of the diet. The iron content of milk is variable, but I should say it is about 0.5 mg. per liter. Suppose a person drinks 2 quarts of milk a day for a year: he is getting in each 2 quarts of milk 1 mg. of iron, and over a period of a year he is getting 365 mg. of iron. That will introduce an element of uncertainty with regard to the absolute minimal amounts of iron that I think would completely nullify the value of this type of study. I don't know whether that was taken into account when that chart was constructed, but it seems to me that an absolute minimal annual intake of iron amounting to 365 mg. of iron would preclude the possibility of saying that the adult human being does not require any iron.

DR. WARREN: That statement was based on the fact that, when patients were placed on as low an intake of iron as could reasonably be given, the lowest being 0.9 mg. a day, no negative iron balance could be demonstrated. They excreted just as much iron as was consumed in the diet.

DR. SUMMERSON: But those facts practically nullify the conclusion indicated by the chart.

DR. WARREN: One must remember that the patient has to be kept in nutritional balance in other respects than iron and that, if a person is starved, then there is a negative iron balance. But the iron excreted under those conditions apparently comes from tissue cells that are broken down and utilized for food during starvation. I think, however, the point you make is well taken, that actually the critical experiments have not been done to establish an absolute zero requirement.

CLINICAL ASPECTS OF IRON THERAPY

DR. DU BOIS: We will go on to the second part, "Clinical Aspects of Iron Therapy and the Choice of Preparations," by Dr. Reznikoff.

DR. PAUL REZNIKOFF: The use of iron in anemia has been clarified to a considerable extent by recent work, but unfortunately the profession at large is still somewhat in the dark as to when to use iron or, more correctly, when to expect an alleviation of the anemia from the use of iron.

Dr. Sabin, in an article on the bone marrow in *Physiological Reviews*, has traced the development of the red blood cell from its earliest stage in the bone marrow to its entrance into the blood stream. At the time when the red blood cell is introduced into the

circulation, the hemoglobin content is at a maximum; this suggests that the amount of hemoglobin in the red blood cell is a factor in determining when the cell is old enough to carry out its functions. In the anemias caused by iron deficiency the problem is to provide the red blood corpuscle with an adequate supply of hemoglobin; and, as Dr. Warren has shown, in most cases that means iron.

When is iron therapy indicated? The answer is, whenever there is a deficiency of iron. Clinically there are relatively few conditions in which iron deficiency occurs, but those few are important. In the first place a deficiency results if iron is lost from the body, as in conditions characterized by chronic hemorrhage. Normally the iron in the blood which is released by disintegration of the red blood cells is used again by the bone marrow; but when there is bleeding a certain amount of iron is lost to the body economy and there is a nutritive defect in the bone marrow so far as iron is concerned. In the second place there is a deficiency if the supply is inadequate. As Dr. Warren has pointed out, the supply is deficient whenever the intake is not high enough to keep the person in positive balance. It stands to reason that, if a child is growing, the child needs iron; if a woman is losing iron through menstruation she needs iron more than if she did not menstruate; and if a woman is pregnant and is supplying iron to the fetus she needs more iron than before she was pregnant. So in the last analysis the question as to whether the intake is inadequate depends entirely on the demand.

That brings up your question again, Dr. Gold, as to whether an iron deficiency anemia could be produced by cutting down on the iron intake of a man who had no hemorrhages. Under those conditions a negative iron balance is rarely observed, and anemia characterized primarily by iron deficiency hardly ever occurs. What is the evidence for that? In Bellevue Hospital we have patients who have been living on coffee and rolls, or coffee and doughnuts, for one, two, three or more years. They come into the hospital with a deficiency disease, such as pellagra or scurvy, but they have practically no anemia. Although they have been on a low iron intake for a great many years, they have very little iron deficiency. So iron deficiency due to faulty ingestion is present only when there is also an increased physiologic demand for iron. Thus the usual clinical types of iron deficiency anemia are the anemias seen in growing children, menstruating women, pregnant women and bleeding patients. An iron deficiency anemia is described in women of the menopausal age, but as Heath and Patek have shown, if those patients are examined carefully they are found almost invariably to have some blood loss.

Should iron be given in acute hemorrhage? As an emergency measure it is certainly not indicated, because in acute hemorrhage there is loss of blood volume and fall in blood pressure, and the problem is really that of circulatory shock. As a matter of fact, it has been shown that after sudden hemorrhage in an otherwise normal person who has sufficient stores of iron, it is not really necessary to give iron at any time. After the hemorrhage has stopped, within a period of several weeks to several months, the red blood cells and hemoglobin will gradually attain their normal level. Iron administration in chronic hemorrhage is of course of other matter.

Are there any other conditions in which iron should be given? Well, it is used in almost every type of

anemia; in fact, most physicians give iron whenever a patient is anemic, and some even use it in pernicious anemia, I think, for no very good reason. Patients who are anemic as the result of chronic infection often receive iron, but this cannot be justified because there is no increase in iron utilization in these cases until the infection subsides, in all probability, because of the depression of the bone marrow. The same is in general true of neoplastic diseases. However, iron sometimes does prove useful in neoplastic disease but that is only when there is chronic hemorrhage in addition to the neoplasm. Again, in chronic nephritis iron is of no use because in this condition there is evidence that we are dealing with a depressed bone marrow, and the only function of iron therapy would be to replace the iron lost in the red blood cells in the urine.

There is a type of anemia called idiopathic hypochromic achlorhydric anemia, which practically always occurs in women. Nearly all give a history of excessive menstrual bleeding, so it is merely the same problem of a loss of blood producing an iron deficiency anemia. But there are undoubtedly a few patients who show but little evidence of blood loss—in fact there may be scanty menstruation—and who still have anemia. Those few patients apparently do well if hydrochloric acid is added to the iron therapy, and they will also have to receive larger amounts of iron than are effective in the ordinary, so-called "iron deficient" person. These cases represent only a small proportion of the patients with so-called idiopathic hypochromic achlorhydric anemia; I want to stress the fact that they are rare. The majority of patients with the achlorhydric type of anemia will absorb iron perfectly well without addition of hydrochloric acid.

I should like to bring up this question of hydrochloric acid now. You may well ask: If hydrochloric acid plays an important role in the absorption of iron, why do not pernicious anemia patients with achlorhydria have iron deficiency anemia? We know they don't. From this we must conclude that only a small proportion of patients with low gastric acidity need hydrochloric acid to facilitate the absorption of iron.

When we give iron how do we know it is effective? By changes in the red blood cell count, in the amount of hemoglobin and also in the reticulocyte count. These changes may be charted as the so-called biologic curve of iron response. Incidentally, the curve is the same for the response of the blood to the administration of liver in pernicious anemia. I should like to illustrate this response by the following experiment: A rat born of a mother which has been on a milk diet for a long time is weaned and put on a milk diet. At birth the rat's blood shows about 3,400,000 red blood cells per cubic millimeter and a little over 6 Gm. of hemoglobin per hundred cubic centimeters. As the young rat continues on the milk diet, the anemia increases, and down go the red count and the hemoglobin percentage, but the reticulocyte count, which is relatively high in the rat, persists at a fairly definite level of between 20 and 25 per cent. However, if iron is given after about the fourth day there is a rise in reticulocytes, which reaches its peak between the fifth and tenth days; this peak may be as high as 40 per cent. The red cell count and hemoglobin begin to rise rather rapidly, so that about three weeks after the beginning of iron therapy, in this case 1 mg. of iron a day, the red cell count and hemoglobin are nearly normal. That is the usual response to iron administration.

How can one tell that iron therapy is going to prove effective? It takes at least two or three weeks to get a really good rise in red cells and hemoglobin. Within a few days after starting the administration of iron, one should follow the reticulocyte count closely, since it early gives a clue as to whether iron therapy will be effective. A rise in the reticulocyte count is always followed by a rise in the level of the red cells and hemoglobin. Furthermore, there is an inverse ratio between the initial hemoglobin level and the reticulocyte peak; in other words, the lower the initial hemoglobin the higher the reticulocyte peak will be within a week after the onset of iron therapy. For example, if a patient has a hemoglobin level of 3.1 Gm. to begin with, one may expect a reticulocyte count of 13 or 14 per cent at the time of the peak; and if the patient starts with a fairly high hemoglobin of 9.3 Gm., the reticulocyte count would be expected to rise only to about 5 per cent. The reticulocyte response is reliable and early evidence hematologically of the impending efficacy of iron therapy. Those types of hypochromic anemia which fail to improve with iron therapy (cases with infections, nephritis, cancer) also fail to show a reticulocyte response to the administration of iron.

How much of a hemoglobin rise can we expect? Here again the rise is inversely proportional to the initial hemoglobin value. If the patient has an initial value of, let us say, 7.5 Gm., which we call 50 per cent of normal, or less than that, we should expect an increase during a three weeks period of an average of at least 1 per cent of hemoglobin daily. In some cases the rate of increase is as high as 2 per cent a day, depending on the dosage of iron and the type of iron used, as I shall show presently. If, on the other hand, the hemoglobin is above 50 or 60 per cent, one would be satisfied with an increase of about 0.5 per cent of hemoglobin a day measured over a three weeks period. These figures are fairly accurate. It is surprising perhaps that the rate of hemoglobin increase should be so mathematical because a considerable proportion of the iron administered may not be transferred directly into hemoglobin but may be stored. The only time you get a quantitative conversion of the entire dose of iron into hemoglobin is when you give it parenterally to patients with anemia. This procedure is unpractical, unnecessary and undesirable in nearly all cases.

THE CHOICE OF PREPARATIONS

Before we take up the relative merits of the different iron products, I want to show you some data assembled from our own clinical studies and those of others, which give some idea of this problem.

Table 1 shows a group of iron products. It does not by any means cover all the different kinds, but there is represented a ferric product, iron and ammonium citrates, and several ferrous products. One type which I have not included is reduced iron, which is metallic iron. I should like to point out that the things one has to take into account in judging the efficacy of an iron preparation include the route of administration, the dosage of iron, the initial hemoglobin level, whether above or below approximately 50 per cent, and the average daily hemoglobin rise over a period of three or four weeks. In most cases after about thirty days of treatment one can calculate the percentage of the iron administered which has been converted into hemoglobin. You see in the table that for the iron and ammonium citrates only about 2 per cent of all the iron given has been converted into hemoglobin. If

you examine some of the ferrous compounds you observe a much larger percentage utilization of iron. Certain ferrous products regularly yield more than 15 per cent utilization. Of course, the greater the dosage the less the percentage utilization; that is obvious because most of it is excreted in the feces. So when only 108 mg. of iron a day was given as ferrous gluconate, the utilization was 37 per cent; but when the dose was doubled the utilization was 17 per cent, or not quite half.

What preparations of iron do we use? Ferrous sulfate, in the form of 0.18 Gm. tablets, is the one we use most frequently in this institution. Each tablet contains between 60 and 65 mg. of iron. Then we have the ferric salt, iron and ammonium citrates, which is put up either in capsules or in 50 per cent solution. We have also a great array of products put up in solutions and in pretty looking pills. There is one which is nothing but ferrous sulfate, a little more expensive because it is pink; and there is one combined with a copper salt, which capsule should not be on the market as an adult medicine. Then we have a product which

* 14.5 Gm. = 100 per cent hemoglobin.

is supposed to contain vitamin B₁, for no good reason at all in my opinion.

Why use ferrous salts? In the first place, as you have heard, the ferrous iron is better absorbed. In the second place, which is very important clinically, it is more easily tolerated in most cases. It does not upset the gastrointestinal tract so readily. Patients receiving iron are apt to complain of vague distress or "indigestion," diarrhea or sometimes constipation. In general the ferrous salts tend to cause less irritation than the ferric.

What about the dosage of iron? I think it is wise in giving a drug which may upset the patient to follow this principle: Start with a small dose and build it up gradually. For example, I plan to give ferrous sulfate, and I want to give the patient nine tablets, that is, about 560 mg. of iron, a day. Instead of starting with three tablets after each meal, I have the patient take one tablet after each meal, and then increase by one tablet a day, so he gets 1-1-1, 2-1-1, 2-2-1, 2-2-2 until the intake reaches 3-3-3, that is, three tablets after each meal. That I think is a good general plan.

Should iron ever be given by injection? Well, "ever" is a big word. I don't know. I should say that I have never myself seen a case or heard of a

case in which iron should be given by injection. Iron has to be given over a long period of time, for about a month at least. Suppose you stick a needle into a patient every day for a month. Although you will all agree it is not pleasant, you will say it is being done constantly with insulin and epinephrine. But the case of iron salts is different: Here you are giving a product which may be quite irritating and may cause necrosis. Even the ferrous compounds, which are relatively nontoxic, may be irritating under some conditions. Furthermore, there is practically no contra-indication to giving iron by mouth, and even patients who have ulcer, or colitis with diarrhea, can take it in this manner. If anything, iron is a styptic, and there should be no hesitation in giving iron by mouth even in a case of bleeding gastric ulcer; at least, I don't hesitate to give it, and I am sure that most physicians feel there is no danger entailed.

I want to speak briefly about the measures for promoting the absorption and utilization of iron. We have mentioned the administration of hydrochloric acid and certain qualifications regarding its use. Then there is the question of other metals, which we shall discuss at length later, but I should like to say here that copper may aid in the utilization of iron under certain special conditions, at least so far as infants are concerned. Practically, it is unimportant because we get all the

not performed. There are a few cases of pernicious anemia which with liver extract therapy show good red blood cell formation without any reticulocyte response to speak of. Those cases of iron deficiency anemia which we have studied carefully and in which we have done daily reticulocyte counts have always shown a rise in reticulocytes, but fewer patients with iron deficiency anemias have been studied in this way than with pernicious anemia.

DR. JANET TRAVELL: I should like to return to the question of the relative effectiveness of ferrous, ferric and metallic iron. I wonder whether the behavior of animals and of human beings is fundamentally different with respect to the various forms of iron. I noticed in table 1 that the dosage of the ferric salt, the iron and ammonium citrates, was from four to ten times greater with respect to the amount of iron that was given than for any of the ferrous salts. In this connection the figures are of interest that were obtained by Whipple and Robscheit-Robbins in their experiments on standard dogs rendered chronically anemic by repeated bleeding. This is the best experimental subject which we have had for the purpose of studying iron deficiency anemia. They found that the percentage of iron appearing as hemoglobin on large and small dosages of iron given by mouth was as shown in table 2. They concluded that all forms of iron are utilized with equal facility by the dog to produce hemoglobin. The determining factor is the dose of iron. This applies not only to iron salts but also to most forms of food iron.

The clinical studies are the ones that are quoted as showing that ferrous iron by mouth is better utilized than ferric iron, and in these studies as a rule equal amounts of iron in the ferric and ferrous forms were not given. When relatively larger quantities of ferric than of ferrous iron were used, the consensus was that no significant difference in the results of the two forms of iron therapy as to blood regeneration was obtained. In all these studies the dosage of iron is relatively large, and it is quite likely that a maximal hemoglobin response was obtained with both forms of the metal. There is a paucity of clinical studies in which identical amounts of iron are given in the ferrous and the ferric forms. A study recently reported by Schlutz, Morse and Oldham was carried out with anemic infants to whom was given 100 mg. of iron either as ferrous sulfate or as ferric and ammonium citrates; when equal amounts of iron were given under identical conditions the ferrous was found to be no more efficacious than the ferric salt. The experiments of Moore and his collaborators seem to point in the opposite direction, namely that ferrous iron is better absorbed than ferric iron. They suggest, however, that diarrhea might occasionally interfere with the absorption of the more irritant ferric salts.

DR. GOLD: May I just mention the fact that Dr. Reznikoff's table seems to me to afford a good basis for the inference that there is no difference in the utilization of ferric and ferrous iron. When 1.2 Gm. of iron was given as ferric ammonium citrate about 2 per cent was utilized, or 24 mg. of iron. When 330 mg. was given in the form of ferrous carbonate, as much as 8 per cent was utilized, or 26 mg. of iron; when a smaller dose of ferrous carbonate was given, 110 mg. of iron a day, as much as 20 per cent was utilized, or 22 mg. of iron. The fact that substantially the same absolute amount was utilized when different amounts were presented to the body indicates that in all cases the doses were probably much too large and

TABLE 2.—Percentage of Iron Appearing as Hemoglobin

Ferric citrate scales.....	5.5	32.0
Reduced iron	3.7	24.5

copper we need in our food, and even as impurities in iron. The liver extract made by Whipple, which is precipitated in 70 per cent alcohol, apparently has an effect in increasing the formation of hemoglobin. How it acts, we don't know. This is not the same product that is used in pernicious anemia. It may also be noted that bile pigment and chlorophyll have been recently shown to aid materially in the production of hemoglobin.

What about food iron? You will read lists of iron-containing foods such as cocoa shell, tea leaf, dried yeast, cocoa as purchased, apricots, egg yolk, liver, oatmeal and spinach, but who wants to eat tea leaves and coffee grounds? One needs to know not only the percentage of iron in these foods but how much iron there is in a portion of food that the patient eats. If you calculate the absolute quantity of iron in an average portion ingested by the patient, then the list of foods runs in a slightly different order: fresh liver, fresh spinach, dried apricots, boiled chicken, fresh lamb, egg yolk, tuna fish, canned and dried prunes, lean beef, canned tomatoes and oatmeal. When you want to prescribe a high iron diet you must determine how much of a particular food the patient is going to eat.

DISCUSSION OF QUESTIONS

DR. DU BOIS: We are now ready for questions.

DR. GOLD: Does iron ever cause an increase in hemoglobin without showing a reticulocyte response first?

DR. REZNIKOFF: I cannot answer that question because in the majority of cases reticulocyte counts are

if a difference did exist in the power of the body to utilize iron from these different sources, these experiments would fail to show it. Don't these figures bear out what Dr. Travell has just said?

DR. TRAVELL: As a basis for comparing the effectiveness of the different iron products, the absolute amount of iron rather than the percentage of the dose utilized for new hemoglobin would seem to be the best criterion.

DR. REZNIKOFF: One thing known from clinical experience is that if you do not give large doses of ferric iron, from 1 to 1.5 Gm. of iron a day, you get practically no results. When we used to give from 100 to 250 mg. of iron as reduced iron or as the ferric salt, we got little hemoglobin response, whereas with no more than 500 mg. of ferrous iron a day we obtain satisfactory utilization. In other words, the trouble with ferric salts and with reduced iron is that the dose in man must be considerably greater than with ferrous iron. In the old days when chlorosis was treated with very small doses of iron it was fortunate that ferrous carbonate was used. Then the dose of iron was 5 mg., and good results were obtained, but it was a ferrous salt.

DR. CATTELL: To complete the discussion of the relative effectiveness of ferrous versus ferric salts, I should like to bring up one more point, that is whether the ferric salt would not be converted into the ferrous form before absorption, since iron is largely absorbed in the duodenum, and whether that might not be an answer to the question.

DR. REZNIKOFF: I think most people agree that no iron is absorbed until it is changed to the ferrous state. That is my impression from the literature.

DR. CATTELL: Under those circumstances does it still make sense that from a therapeutic standpoint the ferric iron should be less effective than the ferrous iron?

DR. REZNIKOFF: From the standpoint of animal experiments it is obviously not less effective, but as I have said when we give very small doses of ferric iron to patients we get little rise in hemoglobin.

DR. TRAVELL: Isn't it true that there may be considerable variation in the response to iron therapy and that some hypochromic anemias fail to respond to relatively small doses even of ferrous iron? Fullerton reported that not all of his cases of hypochromic anemia responded to treatment with ferrous sulfate.

DR. REZNIKOFF: How big was the dose?

DR. TRAVELL: About 150 to 250 mg. of iron.

DR. REZNIKOFF: That is a relatively small dose. Most of us try to give 500 mg. to the adult anemic patient, but we have had excellent responses with as little as 100 mg. of iron a day. On the basis of Minot's figures and our own experience, I am sure that 500 mg. of iron in the form of ferric iron would not cause very much rise in hemoglobin. You have to run the dose of ferric iron up to almost 1 Gm. a day. Practically, the whole question is not very important because we have a cheap form of iron in ferrous iron. We know that it upsets patients much less and that a smaller dose is effective.

DR. TRAVELL: That is true.

DR. CATTELL: I wonder, Dr. Reznikoff, whether it would not be worth while to have a little further discussion of your criteria of dosage and what factors lead you to increase the amounts given. If you do not get

the expected response from the routine dose, do you increase the amount; and if so, to what extent?

DR. REZNIKOFF: It is hard to answer that without taking an individual case. Let us suppose we give a patient 500 mg. of iron a day as ferrous sulfate, and, if she has achlorhydria, we give her hydrochloric acid too, 4 or 5 cc. with each meal. If she does not respond within an adequate time, certainly within three weeks and probably within two weeks, I should try to increase the dose at least 100 mg. of iron a day, probably more.

DR. GOLD: Up to what dose would you go?

DR. REZNIKOFF: Up to the limit of tolerance; in other words, until she begins to get some gastrointestinal upset. I have rarely reached the limit of tolerance, so I do not know what that is except as determined by the individual case.

DR. CATTELL: What dose do you consider adequate for a therapeutic test?

DR. REZNIKOFF: The majority of patients with iron deficiency anemia should respond to about 500 mg. of iron a day in the form of ferrous sulfate. That would be adequate for most patients.

DR. CLAUDE E. FORKNER: I think Heath and his associates stated that the optimal dose for the average adult patient with iron deficiency anemia was 0.8 Gm. of ferrous sulfate daily. In some cases much smaller doses will be effective, in others larger; but that was considered by Heath to be the optimal dose, and that was equivalent to about 6 Gm. of iron and ammonium citrates a day.

SUMMARY

DR. DU BOIS: We can see from the discussions that the subject of iron therapy involves many controversial issues and that to some of the fundamental questions there are no positive answers. Certain points concerning the metabolism of iron are of direct importance in therapy. About 30 per cent of the body iron is present as reserves and this is called on to restore a deficiency in the circulating hemoglobin. After an acute hemorrhage, therefore, iron administration is of little or no value because the body first calls on these stores. When they are used up, as in the case of chronic hemorrhage, iron therapy becomes efficacious in speeding up hemoglobin formation. The discussion has brought out the fact that in the course of normal metabolism of the adult male the loss of iron seems to be negligible. An iron deficiency in the male, therefore, suggests that some form of bleeding must be taking place. It is for this reason that iron deficiency anemias are much more common in females, who lose about 20 mg. of iron with each menstrual period and about 375 mg. of iron with each pregnancy. The experience appears to be that infection reduces the efficacy of iron therapy in restoring deficiency in hemoglobin, but the exact nature of the injury by infection is not understood. We have discussed the question of the value of hydrochloric acid in iron therapy. It is rarely necessary, although some patients appear to require hydrochloric acid to facilitate the utilization of iron. Patients with pernicious anemia have achlorhydria but are not likely to suffer from iron deficiency, while some patients with hypochromic anemia appear to regenerate hemoglobin faster when hydrochloric acid is given together with the iron therapy. We have had a discussion of the question of whether ferrous or ferric salts are superior in the treatment of anemia. There seems to be no complete agreement. There is some good evidence that ferrous salts are better utilized than ferric salts, but some of the

evidence on that point is open to criticism and in some of the studies the clinical efficacy of the two seems to be the same. If there are differences in the utilization of ferrous and ferric salts, it may be that their significance is largely lost in treatment, the doses of iron are so big by comparison with the amounts that are utilized. We need to keep an open mind on this question. There seems to be agreement that iron therapy should be given by mouth and that parenteral administration is rarely necessary. A plan for the use of iron in the treatment of anemia has been outlined. Adequate doses such as 500 mg. of iron a day to adults are likely to be associated with a reticulocyte response. This serves as an index of satisfactory reaction to iron therapy.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

VITAMIN E HAS BEEN CLAIMED TO BE OF VALUE IN THE TREATMENT OF A NUMBER OF VARIOUS DISORDERS, PARTICULARLY WITH REFERENCE TO ITS ALLEGED USEFULNESS IN HABITUAL ABORTIONS. THE COUNCIL ADOPTED THE FOLLOWING REPORT, WHICH WAS PREPARED FOR IT BY THE REFEREE, AND AUTHORIZED PUBLICATION.

PAUL NICHOLAS LEECH, Secretary.

THE TREATMENT OF HABITUAL ABORTION WITH VITAMIN E

Several clinical observers have presented evidence within the last eight years that the administration of vitamin E may enable women who have had repeated abortions to give birth to living children. This evidence, on superficial examination, appears to be good. It is my chief purpose in the present report to subject the evidence to critical examination.

Vitamin E has also been used in the treatment of other disorders of the reproductive organs and of lactation in women.¹ As it seems possible that claims might be made for such uses of vitamin E, it becomes necessary to consider what evidence there is in support of the claims.

VITAMIN E IN THE TREATMENT OF VARIOUS DISORDERS

Involuntary Sterility in Women.—There is no convincing clinical evidence that the administration of vitamin E (wheat germ oil) will enable women with involuntary sterility to conceive (table 1).²

Disorders of Menstruation.—Juhász-Schäffer³ stated that he had administered vitamin E in 150 cases of dysmenorrhea without definite results. Shute⁴ states that he has relieved patients with dysmenorrhea provided their blood showed an increase of estrogenic substance, but he gives no other details.

Toxemia of Pregnancy.—Barrie⁵ claims to have produced "toxemias of pregnancy" in rats fed diets low in

vitamin E. The incidence of toxemia was higher (19 per cent) in animals partially deficient than in those wholly deficient (1.7-2 per cent) or in those receiving adequate amounts of vitamin E (2 per cent). Lesions were found in the liver and kidney resembling the lesions in women with toxemia. Shute⁶ found evidence for vitamin E deficiency in only one of eight women with toxemia.

Faulty Lactation.—Shute⁷ administered wheat germ oil during pregnancy to sixty women considered by him to be deficient in vitamin E; sixteen of these had an unusually abundant secretion of milk for from seven to ten days after parturition; five had scanty secretion; thirty-six were able to nurse their infants for at least three months. Of sixty women who were considered not to be deficient during pregnancy, seven had an unusually abundant secretion of milk, eighteen had a poor secretion and thirty-five were able to nurse for more than three months. Of twenty-three women who could not furnish more than 4 ounces (120 cc.) of milk a day, fifteen had had wheat germ oil during pregnancy. Lactation of six of the fifteen women followed the further administration of wheat germ oil. Two of the eight who had not had wheat germ oil until after delivery had successful lactation following the administration of wheat germ oil.

Vaginal Pruritus.—After the menopause, according to Shute,⁴ vaginal pruritus may be associated with excess of estrogenic substance in the serum. He has reported four cases in which relief followed the use of large daily doses of wheat germ oil.

5	6	10	6	31.5
6	4	10	4	21.7

The formula of Malpas was modified by including the numerical factor which gives the probability of the occurrence of pregnancy.

While the results in case of deficient lactation and in vaginal pruritus are suggestive, it is obvious that much more observation and many more reports from other workers are needed before any claim can be permitted for the value of vitamin E in their treatment.

Before considering the use of vitamin E for the prevention of "habitual abortion," it is necessary to call

attention to the frequency of occurrence of abortions of all types, to the difficulties which naturally exist in ascertaining the frequency of occurrence of the various types of abortion—spontaneous and induced—and, finally, to the lack of published statistics on the frequency of “habitual abortion.”

Taussig⁸ states that 2,400,000 living infants are born in the United States each year and estimates that in each year 682,000 abortions occur. It is impossible to ascertain with any certainty how many abortions are spontaneous and how many are induced. Plass,⁹ analyzing the replies of eighty-one Iowa physicians to a questionnaire, found that, while 51,000 deliveries occurred, there were 10,000 abortions, of which 76 per cent were induced. Brunner and Newton¹⁰ report that 3,216 women had 10,609 pregnancies with 2,897 abortions, of which 42 per cent were induced. Simons¹¹ reports that 40.6 per cent of 995 abortions treated in the hospital were induced. Kopp¹² has published an analysis of 10,000 case histories of women studied by the Birth

Habitual abortion is defined by Bishop¹⁴ as premature delivery on more than one occasion before the fifth month of gestation not due to discoverable disease, organic cause or artificial induction. He found habitual abortion in only eleven (0.41 per cent) of 2,687 pregnant women. Malpas¹⁵ believes that repeated abortion may occur in 1 per cent of all pregnancies. Taussig⁸ and Kopp¹² make no estimate of the frequency.

Taussig states (p. 102) in regard to the etiology of spontaneous abortion: “In this country, where all the needed constituents of a well balanced diet are obtainable, dietary deficiencies probably do not play a very great part in abortion, except in domestic animals.” This view is beyond doubt the prevalent one. The recent publication of a number of observations claiming the cure of repeated abortion by treatment with wheat germ oil therefore deserves critical analysis.

If the effect of measures proposed for the prevention of repeated abortion is to be studied critically, it is necessary to have a definition of repeated abortion and

Control Clinic Research Bureau of New York City. She believes that the number of induced abortions acknowledged by these women is probably too low but is likely to be nearer the truth than in the case of women entering the hospital for obstetric treatment. It should be pointed out, however, that many of the women sought advice for contraception, a fact which might indicate previous more or less successful attempts at abortion. Kopp found that 9,583 women had had 38,985 pregnancies, resulting in 11,172 abortions, of which 72 per cent had been induced. Whitehouse¹³ in England reports that 3,000 women had had 11,430 pregnancies with 17.2 per cent abortions. He did not attempt to ascertain how many of the abortions had been induced. The data of the American authors just quoted show that about 28 per cent of all pregnancies terminate in abortion and that of 25,064 abortions 65 per cent were induced; therefore 9.8 per cent of all pregnancies resulted in noninduced abortion. Possibly about 240,000 noninduced abortions occur each year in the United States. Unfortunately the American reports fail to give adequate details regarding the frequency of repeated abortions.

necessary to know what results might be expected without treatment. No adequate studies of this sort exist. Malpas, in an analysis of abortion sequences based on the data of Whitehouse, remarks that in the great majority of cases abortion occurs but once and must therefore be due to chance. He presents a calculation to show that a nonrecurrent or “chance” cause for abortion occurs in 17 per cent of all pregnancies and that a recurring cause for abortion occurs in 1 per cent of all pregnancies. Examination of his argument, however, indicates that he ignored the fact that the expectation of pregnancy decreases with successive pregnancies. If this fact is taken into account, it can be shown that a “chance” cause occurs in 16 per cent and a repeated cause in 2 per cent of pregnancies (table 2). The assumption in these calculations is that in a certain small proportion of pregnant women abortion will inevitably occur; in them the probability of abortion, p', is equal to 1. A detailed consideration of the original data of Whitehouse will show that a better approximation of theory to the data is afforded by the assumption that in about 7.8 per cent of all pregnancies there is a probability of abortion not equal to unity but to 0.84, whereas in the remainder there is a probability of abortion of p = 0.116.

Table 3 present the data, together with the theoretical results; the table is so constructed as to show in columns N the number of women with no, one, two, three, four,

F, predicted frequency of consecutive abortions; R, proportion of habitual abortions among all abortions; C, per cent of "spontaneous cure" of women who have had indicated number of consecutive abortions. For Malpas's original calculations, $p = 0.17$, $p' = 1$, $b = 0.01$. The weighted averages of the constants in table 2 were used for the other calculations; For Malpas's revised calculations, $p = 0.126$, $p' = 1$, $b = 0.6293$. For the present theory, $p = 0.1164$, $p' = 0.843$, $b = 0.0777$.

being considered, b indicates the proportion of women who would inevitably abort. The values of b and p were calculated by the methods of the theory of probability in such a way that theory and observation agreed for the frequencies of no abortion and of abortions for every pregnancy. It will be observed that the agreement is good in case of two and three pregnancies. This, however, is an inevitable consequence in case of two or three pregnancies and therefore does not prove the correctness of the theory. In case of four, five and six pregnancies the agreement between predicted and actual frequencies is poor. In particular, the actual frequency of more than three abortions often exceeds the theoretical frequency. This discrepancy can in part be

obviated by adopting another theory: that the probability of abortion (p') is somewhat less than unity in a proportion of women (b). In order to calculate p, p' and b according to this theory, the assumptions were made that the theoretical and observed frequencies of no abortion and one abortion should agree and that the total expectancy of abortion in any group should be that calculated from theory. In this way the frequencies and constants in column f_2 were calculated. It is evident that the agreement between observed and calculated values of the frequencies is good.

The weighted means of the constants may be used to predict the probability of consecutive abortions in a sufficiently large group of women. These calculations are presented in table 4. This table shows the predictions both for the original theory of Malpas (I), his revised theory (II) and for the theory presented here (III). In all the theories the probabilities decrease rapidly at first. According to the theory of Malpas the frequency becomes nearly constant after three successive abortions but according to the other theory the frequency decreases indefinitely. According to either theory there is therefore a tendency for a certain calculable proportion of women to "recover" from repeated abortion.

Although the accuracy of the results is open to criticism because of the small number of cases on which the results are based, and although the general applicability of the particular frequencies may be questioned, a few important conclusions may be drawn: 1. The diagnosis of habitual abortion is not justified until a woman has had at least two consecutive abortions. This is indicated by the numbers in the rows marked R. These numbers are the ratios of the frequencies of "habitual abortion" to total abortions and show that after two or three consecutive abortions nearly all the women in the

TABLE 6.—Relationship Between Number of Previous Abortions and Results of Treatment with Wheat Germ Oil

group are subject to "habitual abortion." Since artificial induction and organic disease account for more than 65 per cent of all abortions, these causes must be excluded in the definition of "habitual abortion." 2. Although the diagnosis of repeated abortion might have been made in from 4.5 to 6.8 per cent of the cases considered in this analysis, it seems likely that at least 2.9 per cent of the women were liable to repeated abortion and possible that 7.7 per cent may have been subject to a probability of abortion as great as 0.84. 3. There is a marked tendency to spontaneous cure of repeated abortion. For example, if a woman has had two consecutive abortions, the chances are about 1 to 3 that she will not have another.

The results claimed in the treatment of 175 cases of repeated abortion collected from the literature are presented in tables 5 and 6. The results would seem at first glance to be favorable, for relief of habitual abortion in 75 per cent of cases is indeed a result much better than one would expect without treatment. The greatest objection to accepting the reported results as actual cures lies in the uncertainty of diagnosis of habitual abortion. As I have already demonstrated, the occurrence of a single spontaneous abortion does not establish the diagnosis, and the expectancy in such a case that the next pregnancy will not result in an abortion is about 70 per cent. Even after two successive pregnancies have resulted in abortion there is an expectancy of no abortion in the next pregnancy of about

30 per cent. The reported success of treatment after three successive abortions have occurred is much more impressive. But here one has to consider the possibility that some or even all the abortions had been induced. The authors have been able to furnish satisfactory evidence in only about half of the cases in question that the abortions were spontaneous. There are two important reasons for the lack of this information. First, habitual abortion is infrequent. Consequently, those who are interested in its treatment have included in their reports not only their own cases but also the cases

TABLE 7.—Increased Antitryptic Activity of Serum (Shute)

of practitioners to whom they have furnished wheat germ oil. Second, the reported cases have not often been observed at the time of previous abortions. It seems quite possible that a number of the women may have had abortions induced and later, desiring an infant, may have sought medical advice.

Another difficulty in obtaining evidence of the effect of vitamin E in the prevention of habitual abortion lies in the lack of any exact knowledge of the outcome in the absence of treatment. We have attempted to predict what might be expected, but this prediction is based on a calculation from data admitted to be somewhat inaccurate. Before any claim for the specific effect of vitamin E in the prevention of repeated abortion can be accepted, more exact predictions of the expectancy of spontaneous cure are necessary.

A third difficulty in accepting the published results arises because of the extraordinarily varied amounts of wheat germ oil used by the various observers and because frequently no data are available to prove that the oil was potent.

DOSAGE

The daily dose of wheat germ oil used by five of the authors mentioned in table 5¹⁶ varied from 0.25 to 6 cc. In spite of this variation, the apparent success of treatment was the same. Shute believes that the requirements of pregnant women for vitamin E may be even larger than those already stated and has often given as much as 45 cc. of wheat germ oil a day for two weeks; in one case, 90 cc. was given. Shute bases this belief on his observation that the serum of women who have spontaneous abortion, premature labor and abruptio placentae frequently shows abnormally high antitryptic activity (table 7).¹⁷ He ascribes this to an

excess of estrogenic substance. According to him¹⁸ the excessive antitryptic activity of the serum prevents normal penetration of the fetal villi into the maternal decidua, with resulting interference with fetal nutrition or even premature separation of the placenta with hemorrhage. He⁶ states that sufficient doses of potent wheat germ oil will relieve the symptoms of abruptio placentae in most cases within twenty hours, provided the condition is due to deficiency of vitamin E as indicated by the test for antitryptic activity. He gives illustrations of this but no further data. Although the theory might explain the pathogenesis of vitamin E deficiency in women and would afford a laboratory test for the presence of deficiency, it must be pointed out that no other workers have reported data to confirm it. Cooper¹⁹ believes that Shute's test furnishes a reliable index of the estrogenic content of the serum but gives no data. Cuthbertson and Drummond²⁰ question the reliability of Shute's method²¹ for demonstrating antitryptic activity; they are unable to find an excess of antitryptic activity in the serum of rats with vitamin E deficiency; they used as controls rats receiving adequate diet and diet with excessive amounts of wheat germ oil. The studies were carried out both with Shute's original method and with a viscosimetric method. If much smaller doses of wheat germ oil are really effective in the prevention of threatened abortion (table 8) than those, according to Shute, necessary to reduce the antitryptic activity of the serum, the theory must be questioned.

STABILITY OF VITAMIN E

The potency of wheat germ oil in vitamin E not only is variable but diminishes rapidly at room temperature. For this reason Shute recommends that the pressed oil should be kept in the refrigerator and not be used if more than 8 weeks old.²² Unfortunately no practical methods of assay exist. For these reasons it is difficult to ascribe some of the reported successful results in the treatment of habitual abortion and threatened abortion to vitamin E, especially when used in small doses. The production of synthetic vitamin E and of a more stable acetate²³ may provide investigators with substances that can be used in a critical study of the problems under discussion.

UNFAVORABLE EFFECTS OF WHEAT GERM OIL

Those who advocate the use of small doses of wheat germ oil have reported no ill effects. Shute²² states that the continuous administration of the oil up to the beginning of labor did not delay labor in sixty cases or prolong it in ten cases in which it was given during

the first stage of labor. He has observed irritation of the gastrointestinal tract and rash in only six cases.²⁴ The danger of production of neoplasms²⁵ appears to be nonexistent (Day, Becker and McCollum;²⁶ Evans and Emerson;²⁷ Dingemans and van Eck²⁸).

CONCLUSIONS

Claims that vitamin E (wheat germ oil) is of value in the treatment of menstrual disorders, failure of lactation and the vaginal pruritus after the menopause cannot be accepted because of lack of sufficient clinical evidence.

The claim that vitamin E is of value in the prevention of habitual abortion cannot be accepted because of the lack of convincing clinical evidence. The diagnosis of habitual abortion in many of the published reports is open to question; the great variation in dosage of vitamin E and the lack of evidence that the preparations used were active make it difficult to attribute any effects claimed for it to the vitamin. Moreover, the expectancy of spontaneous cure in cases of so-called habitual abortion has not been accurately established.

Although the administration of wheat germ oil probably does not cause the development of neoplasms, unfavorable effects may follow its use in certain cases. These effects are usually not serious.

The published results of the treatment of habitual abortion with vitamin E are sufficiently encouraging to justify further clinical experiment. Such experiments are justified only if preparations of vitamin E of known activity are used and if adequate diagnosis and clinical control can be established.

Strong Memorial Hospital.

REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
PAUL NICHOLAS LEECH, Secretary.

SNAKE VENOM SOLUTION (MOCCASIN) (Lederle Laboratories, Inc.) NOT ACCEPT- ABLE FOR N. N. R.

In 1935 the Council published a preliminary report on Snake Venom Solution (Moccasin) of the Lederle Laboratories, Inc., which had been submitted for consideration as useful in the treatment of hemorrhagic conditions.¹ The Council found the status of the preparation promising but felt that more adequate evidence was desirable for further consideration. In 1939 the Lederle Laboratories, Inc., called the attention of the Council to the fact that twelve papers on the subject had been published since the Council's report, ten containing evidence for its therapeutic use and two dealing with an intradermal test and the action of the venom on capillary walls.

The Council considered a report of the referee on the later literature. Allergic conditions and hemophilia were excluded as not meriting further consideration. The referee's report abstracted the later literature as follows:

Functional Uterine Bleeding.—Twenty-four cases were considered in the previous report. Goldberger and Peck² reported

good results with the treatment of seventeen of a total of twenty patients. However, these seventeen included twelve whose cases were considered in the first report. Davin and his associates³ administered venom to fifty-one patients and compared the results with those seen on fifty patients who served as controls. They stated that the results were encouraging but that much work remained to be done before the venom could be recommended in every obstetric case.

Idiopathic Epistaxis.—Five cases were considered in the first report; Dack⁴ reported the two cases of himself and a colleague in the hospital; Goldman⁵ reported forty-two cases (including the two reported by Dack) and stated that the venom was effective in arresting or diminishing the amount and frequency of bleeding in practically all cases. Dack was slightly more conservative.

Multiple Hereditary Telangiectasis (Osler's Disease).—Four cases were reported to the Council. Peck, Rosenthal and Erf⁶ reported that the results of the venom test were negative but that two patients showed some improvement with continued treatment with venom.

Thrombocytopenic Purpura Haemorrhagica.—Sixteen cases were considered in the first report. Greenwald in 1935⁷ reported the treatment of three patients with the venom, and in 1938⁸ he reported that these three had remained well and that active bleeding had been stopped in four others treated subsequently.

Tidy¹⁰ applied the venom of Russell's viper locally—not by injection—in three cases, with reported satisfactory results.

Peck, Rosenthal and Erf in 1936¹¹ used venom intradermally as a prognostic test in essential thrombocytopenic purpura; they injected the venom subcutaneously in thirty-four cases of chronic purpura haemorrhagica, with apparently good results in twenty-two. These investigators in 1937¹² injected venom which had been titrated on the chicken embryo by the method of Witebsky, Peck and Neter¹³ intradermally as a test for the fragility of capillaries and stated that the test is helpful in the management of thrombocytopenic purpura, in which it is a guide to local, general and toxic capillary changes. They⁶ classified purpura with special reference to the selection of cases for treatment with venom and reiterated that its effectiveness had been proved during the previous five years.

Rosenthal,¹⁴ who had previously published several papers with Peck and his associates on the use of venom, reviewed the history of 153 cases of thrombocytopenic purpura and classified them according to age, causation and course of the disease. He stated that spontaneous recovery occurred in 38 per cent of acute cases in all age groups. The referee's analysis of the table indicates that 80 per cent of those under 20 years (84 per cent if a case of drug idiosyncrasy is included) recovered "spontaneously." The meaning of the term "spontaneous" used in that paper is not clear, since the 153 cases under discussion included the fifty previously reported to the Council

with which venom was used. In "two typical" cases detailed there is no mention of the use of venom or other drug.

Rosenthal stated that no medical treatment can be regarded as specific; that venom and transfusion are the only acceptable palliatives in chronic thrombopenic purpura, and that venom, which is only palliative, was not responsible for all the improvement which followed its use. He recommends splenectomy in all chronic cases because of the danger of temporizing and because it is curative in the majority of such conditions. He holds that splenectomy is contraindicated in some acute cases and that venom is of diagnostic value. One feels that this paper is somewhat more conservative than some of the earlier ones.

Splenectomy.—It is necessary to consider this subject briefly because its relative value has a direct bearing on the usefulness of venom. Whipple¹⁵ stated that of eight splenectomies performed in the acute stage of thrombocytopenic purpura haemorrhagica seven proved fatal but that there were only six deaths following splenectomy in seventy-three chronic cases. Of sixty-one splenectomies which could be followed the results were good in fifty-one, fair in four and poor in six. This does not take account of the six deaths in the seventy-three cases just mentioned.

It is usual to classify these cases of purpura as acute and chronic, but Rosenthal¹⁴ stated that it is sometimes difficult to predict at the outset whether the disease is of the acute or chronic form. Brown and Elliott¹⁶ stated that the efforts of surgeons to divide thrombocytopenic purpura into acute and chronic have resulted in much confusion. Brown and Elliott stated that the available evidence indicates that the operative mortality is from 13 to 14 per cent in the acute stage and from 5 to 6 per cent in the chronic. The low figures are to be expected only in carefully selected cases with adequate preparation for operation by experienced surgeons.

Andrus and Holman¹⁷ reported the results in fifty splenectomies performed during five years at the New York Hospital. They reported no operative death in seventeen cases of congenital hemolytic jaundice, in twelve of thrombopenic purpura, in two of atypical purpura haemorrhagica, and in eight of Banti's syndrome. The results in the seventeen cases of chronic hemolytic purpura had been followed for periods of from three months to five years. Two patients died; the results were good in fourteen cases and fair in one. The results were good in eleven of the twelve cases of chronic thrombopenic purpura; one patient died after five months. The results were good in four of the eight cases of Banti's syndrome, fair in two and poor in one, and one patient died after two years. The authors stated that the attempt to extend splenectomy beyond the three favorable conditions—congenital hemolytic jaundice, thrombopenic purpura and Banti's syndrome—are attended with higher mortality and disappointing results.

The paper of Andrus and Holman was discussed by Whipple and by Paul Reznikoff. Whipple stated that he had reviewed the cases reported by the authors, the results of which were much like his own at the Presbyterian Hospital in New York; that it seems miraculous to see purpura disappear in from five to ten minutes after splenectomy, and that the term "Banti's syndrome" covers a certain amount of ignorance. Reznikoff stated that thrombopenic purpura gives hematologists a great deal of trouble; that it is often difficult to differentiate it from other diseases; that even necropsy does not always reveal the patient's trouble, and that physicians urge splenectomy after they have reached the end of their rope.

Vaughan and Wright¹⁸ observed six patients for periods of from ten to fifteen years following splenectomy for purpura haemorrhagica; all continued to be free from bleeding phenomena; the best results followed splenectomy when the preoperative diagnosis of recurring idiopathic purpura haemorrhagica was unequivocal. It is significant that they could find

records of only fifty-nine cases in which the results following splenectomy for this condition had been observed for more than five years, though the method had been in use for twenty-three years.

Schnierson, Lyttle and Peck¹⁹ found that venom in the dosage used did not prevent the recurrence of moderate urinary changes in nephritis (subclinical) in twenty-two cases of scarlet fever and that it gave no evidence of causing damage to the renal capillaries. They concluded, therefore, that therapeutic doses do not damage the normal capillaries of the body.

Rosenthal¹⁴ mentions three cases in which the intracutaneous injection of venom induced violent reactions. However, that method of administration is not generally used therapeutically. The previous report considered the frequent occurrence of hypersensitiveness to venom; this has been observed by all who have used it as Peck and his co-workers do. It is not usually a serious matter in the hands of one who is experienced in the use of venom, but a colleague in whose knowledge the referee has confidence holds that really serious reactions are not uncommon.

Brown and Elliott¹⁶ state that it has been 200 years since Werlhof described a case of purpura haemorrhagica; during that time the greatest advance in its treatment was that by splenectomy, and it seems only fair to conclude that further advances will be made in the near future with the better appreciation of the necessity for preoperative diagnosis based on detailed studies of the blood, and other factors, and with more complete statistics showing greater precision in the selection of cases which should be treated palliatively and those in which operation should be performed promptly.

Few deny that venom has some diagnostic and palliative value, but it is impossible at present to determine the extent and limitations of its use, because it is not known when palliative treatment involves greater risk than operation in certain cases. A large part of the literature which the referee has seen comes from Peck and his associates, and only a smaller part, so far as venom is concerned, comes from hematologists not in any way associated with Peck; surgeons appear to give venom scant attention for the conditions under discussion here.

A consultant of extensive experience with venoms has furnished the following statement:

It is difficult for me to give you a simple statement about moccasin venom. I have used it in about half a dozen cases. In at least four of the patients they have reacted with rather small doses to the venom so that at the site of injection their arms were swollen, red and painful. Desensitization of these patients I found to be impracticable because, after reaching a small dose such as 0.25 cc., they again developed local reactions.

My best result was obtained in a patient who had purpura, a bleeding time of twelve minutes, and a decrease in platelets. I was able to give him as much as 1 cc. of the moccasin venom and his bleeding time decreased from twelve to four minutes, but from April 1935 through January 1937 he received moccasin venom in 1 cc. doses as often as three times a week and his bleeding time would fluctuate throughout this period from four to more than fifteen minutes, regardless of the dosage. His last platelet count, taken on March 9, 1939, was 30,000. In view of the fact that I could not consistently keep this man from spontaneous hemorrhage and increased bleeding time, I do not feel that the moccasin venom could be considered a specific palliative reagent.

This subject is further complicated by spontaneous remissions, and in conclusion all I can say is that I do not feel that I am justified in using this venom with any assurance that it would be more effective than any other nonspecific treatment or transfusions. If I had to pass judgment on this for the Council, I would state that its acceptance should still be held up until better proof is obtained for its palliative efficacy.

As a result of the consideration of the referee's abstract and the consultant's statement, the Council reached the following conclusions: (a) that Snake Venom Solution (Moccasin) (Lederle) is not acceptable for New and Nonofficial Remedies because the scope of its usefulness and its limitations have not been established satisfactorily and because its use tends to delay the resort to splenectomy, which is known to be curative in a large percentage of cases of chronic involvement—a delay which may result in death; (b) that the general employment therapeutically of Snake Venom Solution (Moccasin) before its scope and limitations have been determined would do more harm than good and is not in the best interests of the public.

The Council informed the Lederle Laboratories, Inc., of its decision and of its willingness to reconsider when new evidence of the value of the product becomes available.

SATURDAY, JUNE 1, 1940

THE PLATFORM OF THE AMERICAN MEDICAL ASSOCIATION

The American Medical Association advocates:

1. The establishment of an agency of the federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy.
2. The allotment of such funds as the Congress may make available to any state in actual need, for the prevention of disease, the promotion of health and the care of the sick on proof of such need.
3. The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility.
4. The development of a mechanism for meeting the needs of expansion of preventive medical services with local determination of needs and local control of administration.
5. The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration.
6. In the extension of medical services to all the people, the utmost utilization of qualified medical and hospital facilities already established.
7. The continued development of the private practice of medicine, subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability.
8. Expansion of public health and medical services consistent with the American system of democracy.

FAT TRANSPORT IN THE ANIMAL BODY

The mechanisms provided for the transport of various food materials in the blood and across cellular barriers depend on the nature of the foodstuff. While amino acids and the simpler carbohydrates are generally soluble in water, fatty acids and most of their compounds are insoluble in an aqueous medium. For this reason the transportation of fat in the body presents a unique problem. In recent years research workers have resorted to novel methods, involving the use of fatty acids containing isotopes or radioactive elements in studies bearing on this problem; such methods have served to add considerably to our knowledge of the carriage of fat.

In a timely review Bloor¹ has summarized some of the more recent facts and ideas bearing on the problem

of the transport of fat in the body. With regard to the transfer of fat across the intestinal mucous membrane, it may be recalled that normally fat is completely hydrolyzed during its stay in the intestine. The splitting of fats into their constituent parts, glycerin and fatty acids, might be considered as the first stage of fat transport. Although the absorption of unhydrolyzed fat from the intestine under particular conditions has been reported occasionally, in the light of present evidence as regards normal intestinal behavior it seems unlikely that the intact fat molecule is normally absorbed as such. In the presence of bile the fatty acids are soluble in water and are readily absorbed. Microscopic and chemical studies indicate the resynthesis of fat within the intestinal mucosa. The observation that the phospholipids of the mucosa change their fatty acids during fat absorption to correspond to those being absorbed but do not change in amount has led Sinclair² to assume that the absorbed fatty acids are transformed into phospholipid as an essential step in the resynthesis of neutral fat.

Unlike the water soluble metabolites, which are transported to the liver from the intestine, in the main, by way of the portal system, the water insoluble fats are largely absorbed via the lymph and reach the blood indirectly. Whether or not any appreciable amount of fat is absorbed directly into the blood is still a disputed point. It has been reported, however, that there is an increase in the total fatty acids of the blood during fat absorption in animals in which the lymph of the thoracic duct is diverted by fistula. In any case the small fat particles present in the blood, which are recognized as fat in the process of transport, come mainly from the intestine by way of the chyle. Most of the fat absorbed from the intestine reaches the tissues in this form. The increase of phospholipid in the blood during fat absorption has been repeatedly reported, and its occurrence as part of the mechanism of fat transport is also generally accepted. The results of animal experimentation indicate that during fat absorption there is not only an increase in the neutral fat but also a definite, although comparatively small, increase in the phospholipid content of the thoracic lymph.³ Cholesterol is likewise involved in the carriage of fatty acids in the blood as well as in thoracic lymph. At least two thirds of the cholesterol of the plasma is combined with fatty acids as esters and about one fourth of the total fatty acids of the plasma is carried in the form of cholesterol esters. As Bloor, Blake and Bullen⁴ have pointed out, of the three main fatty acid compounds of blood plasma—neutral fat, phospholipid and cholesterol esters—the degree of unsaturation is

1. Bloor, W. R.: Fat Transport in Animal Body, *Physiol. Rev.* **19**: 557 (Oct.) 1939.

found to be greatest for the cholesterol ester fatty acid, next for the phospholipid and lowest for the neutral fat. This might indicate a special function of cholesterol in relation to the metabolism of the unsaturated fatty acids of blood plasma.

It is believed that the liver takes an active part in fat transport. Just as it permits the temporary storage of carbohydrate and protein, so also may the liver act as a temporary storage place for fat when this food-stuff is being absorbed. However, under normal conditions the fat content of the liver does not change a great deal, since the fat which comes to this organ is ordinarily worked over rather promptly and moved elsewhere. Under certain experimental conditions, nevertheless, comparatively large quantities of fat accumulate in the livers of experimental animals, and investigations of this phenomenon have yielded information bearing on the problem of fat transport. As pointed out by Bloor,¹ the fact that choline, but not colamine, is an effective substance in the prevention and cure of certain types of fatty livers would indicate that the phospholipid lecithin, rather than cephalin, is the more important metabolic intermediate in the metabolism of fat in the liver and perhaps in the whole organism. The role of the liver in the formation of ketone bodies is also of interest in connection with the transport of fats, since the production of ketone bodies by this organ is presumably an important factor in the transport of fatty acid fragments on the way to combustion.

Many questions relating to the problem of fat transport yet remain to be answered. It is heartening, however, to note that an ever increasing amount of light is being thrown on this subject as the result of investigative activity. New means of tagging fatty acids and fatty acid compounds have been developed, and the tracing of these compounds in the body has been facilitated.

YELLOW FEVER

The demonstration by the United States Army commission in Cuba under Major Walter Reed of the transmissibility of yellow fever by the mosquito *Aedes aegypti* is a brilliant chapter in the annals of American medicine. Another pioneer contribution of the commission was the disclosure that the blood of a person afflicted with this disease carries the filtrable causative agent during the first few days of illness, whereas the sputum, feces, urine and vomitus of the patient are not infected. The last epidemic of yellow fever in the United States occurred in New Orleans in 1905. At present this dread disease little concerns the general public in this country. Despite its virtual disappearance from the United States, however, the malady continues to be interesting to the medical profession. Recently Bauer,¹ of the International Health Division of the Rockefeller Foundation, has reviewed its status.

For more than twenty years the Rockefeller Foundation has been an important factor in the control of yellow fever in a number of South American republics. During this time many contributions relating to the yellow fever problem have been made by medical men associated with this organization. Unfortunately there is no specific treatment for yellow fever. The strategy of the campaign against the disease has been complicated by the fact that yellow fever, as has been known for a number of years, exists in tropical forests in the absence of *Aedes aegypti* mosquitoes. As pointed out by Bauer, this "jungle yellow fever" is ordinarily restricted to lower animals and is only accidentally transmitted to human beings. Nevertheless, persons who do become infected with the disease, which does not differ essentially from *Aedes aegypti* borne yellow fever, may serve as a source of infection for *Aedes aegypti* mosquitoes on entering a community where these insects occur. The disease may then be further spread by the mosquitoes and an epidemic may be initiated. The Rockefeller Foundation has in recent years shifted its emphasis from temporary anti-*Aedes aegypti* mosquito campaigns to a program which includes not only the prevention of *Aedes aegypti* transmitted yellow fever through rigid control in urban areas but also prevention of jungle yellow fever, as far as possible, through vaccination of exposed persons.² Of the weapons for combating yellow fever which have been developed in the laboratory, there is none more effective than individual vaccination against this disease. The availability of vaccine of satisfactory protective strength is limited by the fact that the substance is labile and tests to determine its activity require special laboratory facilities. Nevertheless, vaccination continues to play a leading part in the control of yellow fever; hundreds of thousands of persons living in places where there is danger of infection have been immunized with yellow fever vaccine.

The development of air travel between the United States and South America has made it more difficult to prevent the introduction of yellow fever into the United States from regions where it is endemic. When the voyage from South America to the United States is made by boat, any yellow fever infection that may be present on board is usually detected en route. When port is reached, appropriate quarantine measures prevent the spread of the disease. Travel by airplane is so much less time consuming than travel by ship, however, that it is now possible for a newly infected person to come to the United States from South America and travel around in this country for two or three days before becoming ill. During the first few days of his illness he may infect *Aedes aegypti* mosquitoes, if they are present in his neighborhood, and an epidemic outbreak of yellow fever may result. Bauer points out that our Southern cities are still infectible, as shown by

1. Bauer, J. H.: *Pub. Health Rep.* 55:362 (March 1) 1940.

2. Fosdick, R. B.: *The Rockefeller Foundation, A Review for 1939*, New York, 1940.

recent epidemics of dengue fever, a disease which is transmitted from one person to another by *Aedes aegypti*, the same mosquito that transmits yellow fever.

Fortunately, officers of the U. S. Public Health Service are fully aware of the new problem presented by the air traffic with South America. Airplanes, like ships, are examined for mosquitoes, and persons who arrive by air or water and who are not in possession of vaccination certificates are kept under surveillance for the remainder of the incubation period. Moreover, the flying personnel of the air lines engaged in traffic with South America are vaccinated against yellow fever. Yellow fever has been banished from our shores for more than three decades. In view of the knowledge we now possess concerning its history, occurrence and control, and with the constant vigilance of officers of the U. S. Public Health Service at our ports of entry, we should be able to prevent a serious recurrence of the disease in the United States.

DIABETES IN PENNSYLVANIA

Strome and Blaine¹ have recently analyzed the trends in mortality from diabetes mellitus in Pennsylvania and in the United States Registration Area. The data for both the United States Registration Area and Pennsylvania were obtained from the Census Bureau reports. The study emphasizes the following facts: 1. Diabetes mortality rates are higher in the United States than in any other major civilized country. 2. Pennsylvania leads the United States with the highest mortality rates in the United States Registration Area. 3. Mortality rates from diabetes are increasing every year. 4. Numerically the recorded deaths from diabetes mellitus are increasing in the United States Registration Area and in Pennsylvania. From 1906 to 1937 the mortality rate from diabetes in the United States Registration Area increased from 12.7 to 23.7 per hundred thousand, an increase of 186 per cent. In Pennsylvania from 1906 to 1937 the mortality rate from diabetes increased from 10.5 to 31.2 per hundred thousand, an increase of 297 per cent. Great as is the increase in diabetes mortality rates in the United States Registration Area, that of Pennsylvania exceeds it by 110 per cent. At the same time the death rates from all causes in the United States Registration Area steadily declined from 1900 to 1938 and in the state of Pennsylvania from 1906 to 1938.

Paradoxical as it may seem, the introduction of insulin therapy has added to the incidence of mortality from diabetes. What has really happened is that the mortality has been shifted from the younger age to the older, for the increase is limited to ages 45 and over. Under the age of 45 there has been a marked lowering of the death rate, undoubtedly due to the introduction of insulin therapy. In addition to saving the lives of young persons with diabetes, insulin has the effect of prolonging the lives of adult and middle-aged diabetic patients.

Since, however, as Dublin once remarked, insulin does not confer immortality, these patients sooner or later succumb to the degenerative diseases of their age, such as pneumonia, cancer, arteriosclerosis and nephritis.

Another item of interest is that women after 35 show a greater increase in the death rate than men of the same age. At the ages of 35 to 44 the excess of the female death rate over that of the male is 26 per cent and it increases rapidly to 85 per cent at ages 45 to 54. The maximum disparity in mortality for the two groups, 115 per cent, occurs in ages past 55.

The chief lesson to be learned from this report is that diabetes today presents a serious and growing public health problem. It is tenth in the list of causes of death. According to Dublin² more women over 55 years of age die of diabetes than of tuberculosis. From 2 to 3 per cent of our present population will ultimately die of diabetes. The situation perhaps is not as alarming as might appear on first consideration. Both Joslin³ and Dublin believe that this increase is partly real and partly apparent. The apparent increase is due to the great extension of medical facilities and an earlier diagnosis. The discovery of insulin created a widespread interest in the disease. More physicians now look for the disease than ever before. Thus more cases are registered as deaths from diabetes rather than from some other cause as actually happened in the past. The real increase in the incidence of diabetes is, however, generally admitted. A definite answer as to the relative importance of the apparent increase and the real increase cannot be given at present. Joslin stresses overweight as the one most important factor in the real increase in the incidence of the disease. This factor has been brought about, according to Joslin, by social forces which are making for the improvement of the standards of life of the population. The introduction of machinery relieved men of much physical work, while the increase in the standards of living brought about a greater consumption of food. Thus two forces operate to disturb the metabolic equilibrium of large numbers of persons.

A satisfactory explanation has not been offered for the much greater death rate for diabetes in women. If Joslin's contention that overweight is the most important etiologic factor be admitted, then the almost universal practice of rigid dieting among American women for the past decade should have had the effect of reducing the mortality among them, which it did not.

Strome and Blaine recommend that: 1. Every man and woman should have periodic health examinations with urinary and blood sugar determination if indicated, most emphatically so after the twenty-fifth year. 2. Death certificates should clearly specify whether a death is from diabetes or with diabetes. 3. A statewide educational program for the physician and carefully

written information for the layman for the perception, diagnosis and treatment of diabetes should be instituted. To this might be added a suggestion by Stafne⁴ that what is more necessary is a wide dissemination of knowledge. He found in a somewhat similar study as a member of the Commission on Diabetes of the Minnesota State Medical Association that 28 per cent of the deaths from diabetes in Minnesota are attributable to uncomplicated diabetic coma. Such preventable deaths indicate failure to make use of established methods.

The epidemiologic or mass approach to the problems of the more important diseases such as tuberculosis, syphilis, heart disease, cancer and diabetes is a step in the right direction. This interesting study has come from the Commission on Diabetes and the Medical Society of Pennsylvania. Its authors, F. P. Strome, director of the Bureau of Vital Statistics, Pennsylvania Department of Health, and B. C. Blaine, chairman of the Commission on Diabetes of the Medical Society of the State of Pennsylvania, are to be congratulated on initiating what promises to be a state by state study of an important health problem.

Current Comment

MANAGEMENT OF ACNE VULGARIS

Six well known dermatologists, questioned recently by the *Journal of Investigative Dermatology*¹ on the management of acne vulgaris, express considerable unanimity and only occasionally a difference of opinion. Thus, all are agreed that endocrine therapy is without value. The vitamins are likewise regarded as valueless except for the general indication of improving the health of the patient. Five of the contributors found that vaccines and toxoids are without value. One contributor states that a staphylococcus toxoid is of value especially in the pustular type. The relation of anemia to acne was considered as casual and not causal. All were agreed that the administration of hematinics has little if any effect on the course of the disease. Roentgen therapy is regarded as a valuable though not a dominant feature in the management. One contributor resorted to it in about 25 per cent of his cases, while another dispensed with it in the majority of his cases. One of the contributors would not employ it under the age of 17 years. Another restricted it to patients above 16 and still another to patients above 15, while two employed it at any age and one employed it occasionally for patients of 12 and even 10 years of age. All are more or less opposed to repetition of a single course. One never gives more than a single course. Another contributor would wait at least one year before repeating and still another prefers to wait two or three years. Results from roentgen therapy varied from excellent to fair and no response. Four contributors did not think that roentgen therapy increased the tendency to pitting and scarring. One even felt that it

had the effect of diminishing the tendency and only one had seen evidence of damage "even under proper dosage." Roentgen therapy was most effective when combined with other measures and was not practiced alone. Four of the contributors stressed the importance of so-called acne surgery. This consisted in opening the pustules and extracting comedones. One did not practice it and one felt that it might aggravate the condition. He believed that sulfur paste was capable of accomplishing the same purpose. The importance of local medicinal treatment is concurred in by all. The topical applications most commonly used are combinations of sulfur, resorcinol or salicylic acid. One of the contributors regularly prescribes 10 per cent kaolin and 10 per cent precipitated sulfur in zinc oxide ointment. One of the contributors obtained 60 per cent of cures in from three to eight months with topical drugs "that keep the skin in constant state of desquamation." Dietary treatment was considered without special value by all except one. This contributor insisted that diet was essential to success in the treatment of acne. He prescribed a low fat diet. Milk was considered the most common offensive substance. Iodine in cooking salt was recommended. Another contributor would cut down the carbohydrates and interdict the use of iodine salt. A middle position is taken by the dermatologist, who would correct the irregularities in the diet and interdict the eating of chocolate and the use of butter. He admits, however, that indiscretions in diet are not the cause or the precipitating factor in acne.

PEMPHIGUS

The highly fatal nature of pemphigus together with its uncertain and unexplained etiology and pathogenesis make it a disease of unusual interest. Talbott and Coombs,¹ in a recent study of thirty-four patients with pemphigus, classify the disease simply as either acute or chronic. Study of the blood of the patients with acute pemphigus showed changes in concentration of constituents consistent with adrenal insufficiency. Patients with either type of pemphigus showed an increase in volume of plasma, blood and interstitial fluid. Ten patients with acute pemphigus were observed with special care and to five of them only supportive treatment was given. Death of all the latter followed in from eleven days to eight weeks after onset of acute symptoms. In two of the three in whom necropsies were performed anatomic changes were demonstrable in the adrenal glands. The other five patients with acute pemphigus were given large amounts of adrenal cortex extract and sodium chloride solution. This procedure was followed in each instance by a remission, which persisted three and one-half and three years respectively in two patients without further specific treatment. In the remaining three the remission lasted only as long as active material was given and eventually this became ineffective. Although these observations do not appear to elucidate the causative factors materially, they do constitute an arresting contribution to the knowledge of pathogenesis.

ORGANIZATION SECTION

MEDICAL LEGISLATION

STATE MEDICAL LEGISLATION

Louisiana

Bill Introduced.—H. 21 proposes to require a physician attending a pregnant woman to take or cause to be taken a sample of her blood within fifteen days of the time of the first examination and to submit the sample to an approved laboratory for a standard serologic test for syphilis. All other persons permitted by law to attend pregnant women but not permitted to take blood samples must cause a sample of blood to be taken by a licensed physician.

MEDICAL BILLS IN CONGRESS

Bills Introduced.—S. 3997, introduced by Senator Reynolds, North Carolina, proposes to authorize the Administrator of Veterans' Affairs to furnish domiciliary care and medical and hospital treatment to any former member of the Army, Navy, Marine Corps or Coast Guard who was not dishonorably discharged therefrom and who received such care or treatment at any Veterans' Administration facility at any time prior to March 20, 1933. S. 4017, introduced by Senator Nye, North

Dakota, proposes that any veteran of any war, who was not dishonorably discharged, suffering from any disability, disease or defect, irrespective of whether such disability, disease or defect was service connected, shall be entitled to receive outpatient treatment at such facilities of the Veterans' Administration within the limitations of such facilities, under such regulations as the Administrator of Veterans' Affairs shall prescribe.

DISTRICT OF COLUMBIA

Change in Status.—S. 2013 has been reported to the Senate, with amendments, proposing to amend the Code of the District of Columbia to provide for the organization and regulation of cooperative associations. The Senate Committee on the District of Columbia, in reporting the bill, recommended that there be stricken from it the following sentence: "In the case of an association formed hereunder which arranges the rendering to its members, of licensed professional services on a non-profit basis, said association shall not be subject to the insurance laws, shall not be construed as being in violation of any rule against corporate practice of professions, or in violation of statutes regulating licensure of professions."

OFFICIAL NOTES

THE NEW YORK SESSION

Special Radio Programs

The following radio programs have been arranged in connection with the annual session of the American Medical Association in New York.

Dr. Rock Sleyster, President of the Association, will broadcast over the Columbia Broadcasting System, Wednesday, June 12, from 10:15 to 10:30 p. m., eastern daylight saving time. His subject will be "The American Medical Association and Health Education." Dr. Nathan B. Van Etten, President-Elect, will broadcast over the Blue Network of the National Broadcasting Company, Tuesday, June 11, from 5:15 to 5:30 p. m. His subject will be "American Doctors and American People." Dr. Van Etten will also participate in the "Adventures in Science" program over the Columbia Broadcasting System on Thursday, June 13, from 4 to 4:15 p. m. Dr. Sleyster's talk will be translated and rebroadcast in Yiddish and in Italian.

The programs to be broadcast from New York, with stations, speakers, dates and topics, all on eastern daylight saving time, are as follows:

SATURDAY, JUNE 8:

Station WABC (CBS), 1:15-1:30 p. m. Dr. Philip Lewin, Chicago, "One Pair of Legs Must Last a Lifetime."

MONDAY, JUNE 10:

Station WQXR, 10:30-10:45 a. m. Dr. Harold C. Voris, Chicago, "Head Injuries."

Station WOV, 1:15-1:30 p. m. Dr. Vincenzo Fanoni, New York, will broadcast an Italian translation of Dr. Sleyster's talk "The American Medical Association and Health Education."

Station WOR, 2:45-3 p. m. Dr. Chevalier Jackson, Philadelphia, "Removing Foreign Bodies From the Lungs." Dr. Morris Fishbein or Dr. W. W. Bauer, Chicago, "News of the Meeting."

TUESDAY, JUNE 11:

Station WEVD, 10-10:15 p. m. Dr. L. B. LaPlace, Philadelphia, "Heart Disease."

Station WMCA, 11:15-11:30 a. m. Dr. Wallace E. Herrell, Rochester, Minn., "Sulfanilamide."

Station WOR, 3-3:15 p. m. Dr. A. H. Bulbulian, Rochester, Minn., "Restoring Facial Defects." Dr. Morris Fishbein or Dr. W. W. Bauer, Chicago, "News of the Meeting."

Blue Network, National Broadcasting Company, 5:15-5:30 p. m. Dr. Nathan B. Van Etten, "American Doctors and American People."

WEDNESDAY, JUNE 12:

Station WABC, Columbia Broadcasting System, 10:15-10:30 p. m. Dr. Rock Sleyster, Wauwatosa, Wis., "The American Medical Association and Health Education."

Station WQXR, 4:15-4:30 p. m. Dr. Elliott Joslin, Boston, "Diabetes."

THURSDAY, JUNE 13:

Station WNYC, 11:45 a. m.-12 noon. Dr. Carl Badgley, Ann Arbor, Mich., "Pain in the Back."

Station WNYC, 1:30-1:45 p. m. Dr. John A. Toomey, Cleveland, "Prevention of Communicable Disease."

Station WABC, Columbia Broadcasting System, 4-4:15 p. m. Dr. Nathan B. Van Etten, "Adventures in Science."

Blue network, National Broadcasting Company, 5:15-5:30 p. m. Dr. Morris Fishbein or Dr. W. W. Bauer, Chicago, "News of the Meeting."

FRIDAY, JUNE 14:

Station WOR (MBS), 10:30-10:45 a. m. Dr. Albert E. Sloane, Boston, "School Children's Eyes."

Station WQXR, 11-11:15 a. m. Dr. L. S. Selling, Detroit, "Who Has Traffic Accidents, and Why?"

Station WNYC, 11:45 a. m.-12 noon. Dr. Kellogg Speed, Chicago, "What a Broken Bone Really Means."

SATURDAY, JUNE 15:

Station WEVD, 2:45-3 p. m. Dr. H. L. Gordon, New York, will broadcast a Yiddish translation of Dr. Sleyster's talk "The American Medical Association and Health Education."

A radio talk on "Pneumonia" by Dr. H. F. Flippin of Philadelphia will be broadcast at a time to be announced later.

ORGANIZATION SECTION

ADDRESSES BY OFFICIAL STAFF

DR. W. W. BAUER:

- June 11—Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association, Symposium, New York City.
- June 18—Borrowed Time Club, Evanston, Ill.
- June 26—Milwaukee Hospital School of Nursing, Milwaukee.

DR. MORRIS FISHBEIN:

- June 2—Council of Negro Organizations, Chicago.
- June 6—Rush Medical Alumni, Chicago.
- June 7—Bergen County Medical Society, New Jersey.
- June 11—Woman's Auxiliary, New York City.
- June 23-24-25—Maine Medical Association, Rangeley, Maine.
- June 26—New Jersey Pharmaceutical Association, Asbury Park.

WOMAN'S AUXILIARY

Colorado

The directors of the auxiliary to the Colorado State Medical Society met in Denver, February 8, with thirty-six members present. The most important project of the auxiliary is its benevolent fund for doctors' families in need. The auxiliary has raised \$3,052 for the fund, which was established about six years ago. Also, a special activity of the auxiliaries in Colorado has been the placing of *Hygieia* in schools and public libraries.

Oregon

Members of the auxiliary to the Josephine County Medical Society meet regularly to sew for the Josephine County General Hospital in Grant Pass. The auxiliary to the Lane County Medical Society has placed *Hygieia* in the libraries of twenty-seven schools in the county. The auxiliary to the Multnomah County Medical Society maintains a student loan fund, which is used by a student at the University of Oregon Medical School. The study group of the auxiliary in October discussed a paper on "Occupational Therapy."

Pennsylvania

The auxiliary to the Allegheny County Medical Society met in Pittsburgh January 23. Miss Frances Shirley, who is in charge of the Industrial Home for Crippled Children, spoke on "The Care of Crippled Children." Dr. Walter F. Donaldson, secretary, Medical Society of the State of Pennsylvania, discussed socialized medicine.

The auxiliary to the Beaver County Medical Society has placed *Hygieia* in the high schools of the county and has made gifts totaling \$110 to the county institutions.

At the fourth annual health conference of the auxiliary to the Berks County Medical Society in Reading, January 8, Dr. O. Paul Holmer, director of the Child Guidance Institute of Berks County, discussed "Normal Activities of the Adolescent Boy and Girl"; Dr. Fred B. Nugent, chief of the gynecology department of Reading Hospital, "Preparing for a Normal Menopause"; Dr. Edward L. Bortz, chairman, Commission for the Study of Pneumonia Control, Medical Society of the State of Pennsylvania, "The Doctor Looks at Pneumonia"; Dr. George R. Clammer, pediatrics department of St. Joseph Hospital, Reading, "Preparing the Preschool Child to Face the World," and Dr. Robert J. Phifer, clinical director Wernersville State Hospital, "Psychiatry." A health film was shown and awards were presented to winners of the essay contest on the subject "Why General Good Health is an Asset" by Dr. Charles E. Lerch, president of the Berks County Medical Society.

Texas

The auxiliary to the El Paso County Medical Society met in El Paso January 8. Mr. R. E. Sherman spoke on housing and slum clearance. At a meeting, February 12, there was a discussion on socialized medicine. The auxiliary made the following donations: to the Baby Sanatorium at Cloudcroft, New Mexico, \$75; to the student loan fund of the state auxiliary \$25, and to the memorial fund of the state auxiliary \$25. The auxiliary to the Bexar County Medical Society observed its annual public relations day with a luncheon on the roof of the Plaza Hotel, San Antonio. Speakers were Dr. Herbert Hill, president of the Bexar County Medical Society, and Dr. Francisco Del Rio y Canedo, who spoke on "Medicine in Mexico," illustrated by a motion picture. The auxiliary entered

tained ladies accompanying their husbands to the International Post Graduate Medical Assembly with a Mexican supper on January 23, with 125 guests in attendance. More than 200 ladies attended the tea for new members of the auxiliary at the Medical Library February 2. At the annual "Bring Your Husband" luncheon, February 9, speakers were Mrs. S. H. Watson, president of the auxiliary to the State Medical Association of Texas, and Dr. Sam E. Thompson. Dr. Thompson's subject was "Ethics for a Doctor's Wife."

The auxiliary to the Henderson County Medical Society met in Chandler, January 9, at the home of Mrs. J. F. Baugh. Dr. Gideon Francis Moon spoke on "Medicine, Yesterday and Today."

The auxiliary to the Hunt-Rockwall-Rains Counties Medical Society met in Greenville January 2. "Safety First," by Alvin Knight, was reviewed.

At a meeting of the auxiliary to the Johnson County Medical Society in Cleburne recently Mrs. R. W. Kimbro read a paper entitled "A Visit to Some European Clinics."

The auxiliary to the Kerr-Kendall-Gillespie-Bandera Medical Society has given complimentary renewal subscriptions to *Hygieia* to the public schools in these counties.

The auxiliary to the Tarrant County Medical Society met in Fort Worth January 12. Mrs. E. M. Wier spoke on "Marihuana: Evil Effects of Its Use on Youth." The auxiliary observed Doctor's Day, with a dinner, dancing and a hobby show at the Woman's Club, Fort Worth, February 9.

Washington

Mrs. L. S. Roach, president of the auxiliary to the Washington State Medical Association, spoke on the aims of the auxiliary at a meeting of the auxiliary to the Grays Harbor County Medical Society in Aberdeen January 17.

Miss Mary Huston, head of Whitman College Infirmary, talked on the status of nursing and medicine in Puerto Rico at a meeting of the auxiliary to the Walla Walla County Medical Society in Walla Walla January 15.

Articles from *Hygieia* were reviewed and medical current events given at a meeting of the auxiliary to the Clark County Medical Society at the home of Mrs. Charles Otto, near Vancouver, January 9.

Wisconsin

The auxiliary to the Dane County Medical Society held its January meeting in Madison. Mr. G. B. Larson spoke on hospital insurance. The booklet "The Doctor's Wife," by Dr. Rock Steyster, President of the American Medical Association, was read.

At a recent meeting of the auxiliary to the Fond du Lac County Medical Society in Fond du Lac, members voted to give twenty complimentary subscriptions to *Hygieia* to be placed in schools and libraries of the county.

At the February meeting of the auxiliary to the Kenosha County Medical Society in Kenosha, Mr. Nicholas Magaro gave a talk, illustrated by moving pictures, of his trip to Italy.

Dr. W. M. Jermain, president of the Milwaukee County Medical Society, discussed the functions of the auxiliary, and Mr. James O. Kelley, executive secretary of the society, spoke on "What Every Doctor's Wife Should Know" at a meeting of the auxiliary to the society in Milwaukee February 9.

The January meeting of the auxiliary to the Washington-Ozaukee County Medical Society was held in Richfield. The auxiliary has given twenty-six complimentary subscriptions to *Hygieia* to schools and hospitals in the two counties.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

Tuberculosis Society Elects Officers.—The Arkansas Tuberculosis Association recently elected the following officers, among others: Drs. Augustus C. Shipp, Little Rock, president, and Solomon F. Hoge, Little Rock, secretary-treasurer.

State Medical Meeting and Election.—Dr. Herbert Fay H. Jones, Little Rock, was chosen president-elect of the Arkansas Medical Society at its sixty-fifth annual session in Fort Smith, and Dr. Henry T. Smith, McGehee, was installed as president. Other officers include Drs. Ira Fulton Jones, Fort Smith; Henry V. Kirby, Harrison, and Charles W. Dixon, Gould, vice presidents; Royal J. Calcote, Little Rock, treasurer, and William R. Brooksher, Fort Smith, secretary. The 1941 session will be in Little Rock, April 14-16. Included among the out of state speakers at the meeting were:

- Dr. Edward H. Skinner, Kansas City, Mo., who addressed a public meeting, The Priceless American Heritage of Health and Happiness.
- Dr. Ira H. Lockwood, Kansas City, Mo., The X-Ray Examination in Ileus and Intestinal Obstruction.
- Dr. Meyer Wiener, St. Louis, What Do the Ophthalmologist and General Practitioner Expect of Each Other?
- Dr. William P. Sadler, Minneapolis, The Climacteric: Some Phases in Its Management.
- Dr. John J. Shea, Memphis, Tenn., The Management of Mastoid Complications.
- Dr. James B. Stanford, Memphis, Tenn., Fundus Examination as an Aid in Diagnosis and Prognosis of General Disease.
- Dr. John H. Connell, New Orleans, The Advantages of Serum Transfusions Over Other Intravenous Vehicles.

COLORADO

Society News.—Dr. Dwight B. Shaw presented a "Diagnostic Résumé of Appendicitis" before the Pueblo County Medical Society, April 16, in Pueblo. Dr. William F. Singer discussed "Medical, Economic and Social Progress in a Changing World" before the society, April 2.—The San Luis Valley Medical Society was addressed, April 16, by Dr. Delmer E. Johnson, San Luis, on psychotherapy.—Dr. James Murray Scott, Kalamazoo, Mich., addressed the Medical Society of the City and County of Denver, May 7, on "Ovulation and the Effects of the Gonadotropic Hormone of Pregnant Mare's Serum." Dr. Joseph S. Barr, Boston, addressed a special meeting of the society, May 10, on "Relationship of Ruptured Intervertebral Disks to Low Back and Sciatic Pain."

DELAWARE

Banquet Marks Tenth Anniversary of Academy.—A banquet was held, May 9, to observe the tenth anniversary of the founding of the Delaware Academy of Medicine, Wilmington. The guest speaker was Dr. Oliver Hazard Perry Pepper, Philadelphia, and Dr. Lewis B. Flinn, president of the academy, was the toastmaster. Other speakers included Dr. William H. Kraemer, who gave a short summary of the academy's history, and Charles M. A. Stine, Ph.D. Governor Richard C. McMullen was expected to attend.

DISTRICT OF COLUMBIA

Quality Factors in Pediatric Service.—A regional meeting of the American Academy of Pediatrics, April 4, in Washington, was devoted to a panel discussion of "Factors Influencing the Quality of Medical Care in the Various Types of Pediatric Service." The speakers included Drs. Alexander T. Martin, New York; Frederick F. Tisdall, Toronto; Adolph G. G. DeSanctis, New York; Harold H. Mitchell, Long Island City, N. Y., and Jessie M. Bierman and Martha M. Eliot, Washington.

Society News.—Dr. Paul D. White, Boston, addressed the Academy of Medicine of Washington, May 16, on "The Heart in Middle Life." Dr. Warren F. Draper, assistant surgeon general, U. S. Public Health Service, Washington, has been elected president of the academy.—Dr. Isaac A. Bigger, Richmond, Va., discussed "Traumatic Surgery of the Thorax" before a meeting of the medical and dental officers of the navy on duty in the District of Columbia and vicinity, April 1.—on the Washington Ophthalmological Society was addressed, recently, by Drs. Avery D. Prangen, Rochester, Minn., on "Some Salient Features in the Surgical Treatment of Extra-

ocular Muscles"; Georgiana M. D. Theobald, Oak Park, Ill., "Origin of Choroidal Tumors," and Cecil S. O'Brien, Iowa City, "Carcinoma of the Eyelids."—Included among the speakers before the Washington Society of Pathologists recently were Drs. Thomas F. Crahan, "Curettings from Skin Sinus"; Lester Neuman, "Tumor of Testicle," and William W. Hurteau, "Brain Tumor."

ILLINOIS

Personal.—Friends, relatives and medical colleagues gave a dinner and reception recently to celebrate the fiftieth anniversary in the practice of medicine of Dr. Thomas H. Culhane, Rockford.—Several affairs were held recently to observe the completion of fifty years in the practice of medicine of Dr. Henry O. Munson, Rushville, including a testimonial dinner in Rushville, April 12, at which the fifty year medals of the Illinois State Medical Society were presented to him and to Dr. Albert R. Lyles, Virginia, who also has completed fifty years as a physician. Dr. James H. Hutton, Chicago, president of the state society, was the guest speaker and the guests included Dr. Harold M. Camp, Monmouth, secretary of the society, and other members.

New Society of Pathologists.—The Illinois Society of Pathologists was organized at a meeting in Chicago, April 6, with Dr. Josiah J. Moore, Chicago, as president; Dr. Oscar T. Schultz, Evanston, vice president, and Dr. Israel Davidsohn, Chicago, secretary-treasurer. Its object will be to promote the advancement of anatomic and clinical pathology, to facilitate friendly and ethical relations between pathologists, to promote a clearer understanding of the position of the pathologist and his technical assistants in the hospital, to study economic conditions in relation to the practice of pathology, to stimulate scientific investigation and to promote the practice of scientific medicine by a wider application of clinical and laboratory methods to the diagnosis and prevention of disease. It is planned to hold two meetings a year, one during the annual meeting of the Illinois State Medical Society and one in the fall in Chicago. The first scientific program was presented at the state meeting in Peoria, Tuesday, May 21, with the following speakers: Dr. Victor Levine, Chicago, on "Value of Routine Serologic Tests"; Dr. Frank B. Queen, Chicago, "Value of Biopsy," and Dr. Hubbard Prather Saunders, Chicago, "Organization and Function of Tumor Clinic in Voluntary Hospitals." Dr. Edwin F. Hirsch, Chicago, conducted a clinicopathologic conference.

Chicago

Alumni Day at Illinois.—Alumni Day will be observed at the University of Illinois College of Medicine, June 6. In the morning the medical alumni association and the faculty will present a clinical program at the Illinois Research and Educational Hospital. Open house will be held in the afternoon and in the evening the annual banquet will be held at the Chicago Towers Club. Dr. Michael H. Streicher is secretary of the alumni association.

Two Million Dollars for New Hospital.—Under the will of the late Margaret Gray Morton, Northwestern University will receive more than \$2,000,000 to erect and endow the Morton Memorial Hospital on the Chicago campus, newspapers recently reported. The will provided also that the bequest be used for medical research. According to the report the new hospital, the fourth medical unit on the Chicago campus, will be built on property owned by the university to the east of Passavant Hospital on East Superior Street, but no date was given when construction was expected to begin. Mrs. Morton was the widow of Joy Morton, financier and founder of the Morton Salt Company.

Society News.—The Chicago Urological Society was addressed, May 23, by Drs. Donald B. Douglas, Waukegan, on "Neurogenic Bladder with Special Reference to the Atonic Type"; Frederick Lieberthal, "Mechanism of Ureteral Obstruction in Prolapse of the Uterus," and Donald K. Hibbs and George Shropshire, "Genito-Infectious Lesions Complicating Gonorrhea."—The Chicago Orthopaedic Society was addressed at its annual meeting, April 12, by Drs. George E. Wakerlin on "Recent Advances in Calcium Metabolism"; Lyman W. Smith, "Effect of Time on the Holding Power of Screws in Bone," and Carlo S. Scuderi, "Fat Embolism—An Experimental and Clinical Study."—Among others, Dr. Franklin F. Snyder addressed the Chicago Gynecological Society, May 17, on "The Rate of Entrance of Amniotic Fluid into the Pulmonary Alveoli During Fetal Respiration." Dr. Albert H. Aldridge, New York, discussed "Retroposition of the Uterus in Relation to Pregnancy, with Special Reference to the Technic and End Results of the Bissell Operation" before the society, April 19, among other speakers.

IOWA

District Meeting.—The annual meeting of the Iowa and Illinois Central District Medical Association was held at the Outing Club in Davenport, May 16. The speakers were: Dr. August A. Werner, St. Louis, Anterior Pituitary Gonad Relation; Dr. John J. Shea, Memphis, Tenn., Management of Tonsil and Adenoid Surgery; Dr. Italo F. Volini, Chicago, A Survey of Heart Disease; Dr. Charles G. Farnum, Peoria, Ill., Some Original Medical Poems Entitled "Nonsense in Rhyme"; Dr. Walter C. Alvarez, Rochester, Minn., How Medicine Began.

KANSAS

Society News.—Dr. Earl C. Padgett, Kansas City, Mo., addressed the Shawnee County Medical Society, April 1, on "Calibrated Intermediate Skin Grafts." The speakers before the Golden Belt Medical Society in Junction City, April 4, were Drs. Edward H. Skinner, Kansas City, Mo., on "Treatment and Management of Cancer of the Uterine Cervix"; Manuel Grodinsky, Omaha, "Infection of the Hand and Foot"; Manuel M. Carr, Junction City, "Lipoid Pneumonia," and Leslie L. Saylor, Topeka, "Gas Bacillus Infection."

LOUISIANA

Personal.—Dr. Lewis C. Spencer, Harrisburg, has been appointed director of the Vermilion Parish Health Unit with headquarters in Abbeville, succeeding Dr. Murphy M. Sims, resigned. The unit was in charge of Dr. James A. Coleman, New Orleans, pending the appointment of Dr. Spencer. Dr. Maurice Campagna, New Orleans, has been appointed medical director of the Orleans Tuberculosis Hospital.

State Medical Election.—Dr. Paul King Rand, Alexandria, was chosen president-elect of the Louisiana State Medical Society at its annual session in April and Dr. Christian Grenes Cole, New Orleans, was installed as president. Other officers are Drs. Henry Ashton Thomas, New Orleans; Daniel J. Murphy, New Orleans, and Dawson T. Martin, Donaldsonville, vice presidents, and Dr. Paul T. Talbot, New Orleans, secretary-treasurer.

MARYLAND

Personal.—Dr. Charles E. Gill, formerly of Boston, district health officer in the department of public health of Massachusetts, has been appointed health officer of Prince Georges County to succeed Dr. Archie B. Hooton, who resigned recently to go to South Carolina. Dr. Walter B. Johnson, Cumberland, has been appointed health officer of Caroline County, with headquarters at Denton. Dr. Alfred C. Moore was recently appointed full time medical health officer in the Baltimore health department. He is the seventh full time officer to be appointed.

State Medical Meeting and Election.—Dr. Harvey B. Stone, Baltimore, was chosen president of the Medical and Chirurgical Faculty of Maryland at its annual meeting in Baltimore, April 23-24, to take office Jan. 1, 1941. Dr. Edward P. Thomas, Frederick, is now president. Dr. Richard T. Shackelford, Baltimore, is secretary. The 1941 annual session will be in Baltimore, April 22-23. The scientific program at the recent session included the following speakers:

Dr. Thomas, The Hospital in the Smaller Centers.
Dr. Howard F. Kane, Washington, D. C., Prenatal Care.
Dr. Daniel S. Fisher, Salisbury, Meeting the Problem of the Premature Infant in Rural Districts.
Dr. Houston S. Everett, Baltimore, Some Gynecologic Aspects of Hypertension.

Dr. Edward D. Churchill, John Homans professor of surgery, Harvard Medical School, Boston, delivered one Trimble Lecture on "Pulmonary Resection" and Dr. Elliott P. Joslin, Boston, one on "The Growing Problem of Diabetes and How to Meet It." A series of "practical up-to-the-minute talks" was presented. Twenty speakers participated in the round table luncheon.

MASSACHUSETTS

Conference on Mental Hygiene.—The Western Massachusetts Conference on Mental Hygiene in Education and Social Work was held at the Hotel Kimball in Springfield, April 12-13. One session was devoted to education and one to social work. Dr. Frederick H. Allen, Philadelphia, addressed the dinner meeting on "Value of a Mental Hygiene Clinic to a Community," and Dr. Ira S. Wile, New York, a luncheon session on "Mental Hygiene in the Field of Education."

MICHIGAN

Society News.—Dr. James Milton Robb, Detroit, addressed the Genesee County Medical Society in Flint, recently, on "The Blocked Nose." Dr. Albert H. Montgomery, Chicago, discussed "Abdominal Tumors in Childhood" before the Calhoun County Medical Society, April 2, in Battle Creek. Dr. Elisha S. Gurdjian, Detroit, discussed "Cranial Injuries" before the Jackson County Medical Society in Jackson, April 16.

Alumni Reunion.—The annual clinic and alumni reunion of the Alumni Association of Wayne University College of Medicine will be held in Detroit, June 12-13. Round table discussions will be conducted by the following, all of Detroit:

New Drugs and Vitamins, Arthur H. Smith, Ph.D.
Preoperative and Postoperative Care, Dr. Alexander W. Blain.
Cardiorenal Diseases, Dr. Edgar H. Norris.
Gastrointestinal Diseases, Dr. Clyde E. Vreeland.
Fractures, Dr. Alfred D. La Ferte.
Obstetrics and Infant Resuscitation, Dr. Harold Henderson.

Reunions of the classes graduating in 1890, 1895, 1900, 1905, 1910, 1915, 1920, 1925, 1930 and 1935 will be held.

MINNESOTA

Course on Surgical Pathology.—The department of Pathology, University of Minnesota Medical School, Minneapolis, is offering a course on surgical pathology, June 17-July 26, designed to give a comprehensive review of the lesions shown in surgical specimens. Special emphasis will be placed on the diagnosis of tumors or lesions which may be confused with tumors. The daily class period is three hours but for any one who wishes to do extra work in some field material will be provided. The course is open to any one who has finished the regular medical course in pathology but is especially intended for hospital pathologists and those who wish a course to aid them in preparing for the examinations of the special boards. Establishment of a clinic in connection with this course is under consideration. Dr. James S. McCartney, associate professor of pathology, is in charge.

MISSOURI

Society News.—The Jackson County Medical Society was addressed, April 23, by Drs. Cecil G. Leitch and Russell W. Kerr on "Recent Advances in the Clinical Pathologic Interpretation of Diseases of the Blood with Special Attention Paid to Abnormal Bleeding, Vitamin K and Prothrombin Paid to Abnormal Bleeding." The Kansas City Southwest Pediatric Society was addressed, April 16, by F. Copeland Shelden, D.D.S., on "Some Considerations of Malocclusion and Facial Disharmony in the Growing Child," and Dr. Earl C. Padgett, "Some Phases of Reconstructive Surgery in Infancy and Adolescence." The Association of Military Surgeons was addressed in Kansas City, April 17, by Lieut. Col. Daniel S. Lockwood, dental corps, U. S. Army, Station Hospital, Fort Leavenworth, Kan., on "Dental Practice in Military Service." Dr. Frederick V. Emmert, St. Louis, discussed "Management of Difficult County Cases by the General Practitioner" before the St. Louis County Medical Society, April 24. Dr. Allen O. Whipple, New York, addressed the Kansas City Academy of Medicine recently on "The Application of Chemistry to Certain Problems in the Preoperative and Postoperative Care of Surgical Patients."

MONTANA

Postgraduate Sessions in Obstetrics and Pediatrics.—The Montana State Medical Association and the Montana State Board of Health are conducting a series of postgraduate lectures throughout the state. The lecturers are Drs. William F. Mengert and Julian D. Boyd, associate professor of obstetrics and gynecology and associate professor of pediatrics, respectively, State University of Iowa College of Medicine, Iowa City. Their subjects are:

Normal Nutrition in Childhood.
Minor Ailments of Pregnancy.
Infant Feeding.
Management of Normal Labor; Puerperium.
Immediate Care of the Newborn; Prematurity.
Examination of Newborn and Resuscitation.
Treatment of Well Child Demonstration.
Abortion.
Treatment of Upper Respiratory Infections.
Treatment of Diarrheas.
Obstetric Hemorrhage; Placenta Praevia and Premature Separation of Normally Implanted Placenta; Postpartum Hemorrhage, Immediate (Otoky, Retention, Tears) and Delayed.

The program was presented in Billings, May 24-25; Butte, May 27-28; Missoula, May 29-30; Kalispell, May 31-June 1, and will be continued in Havre, June 3-4; Great Falls, June 5-6; Lewistown, June 7-8, and Glendive, June 10-11.

NEW JERSEY

Society News.—Dr. Temple S. Fay, Philadelphia, addressed the annual meeting of the Passaic County Medical Society, Paterson, May 9, on "Refrigeration for the Control of Cancer." The meeting was held in cooperation with the local committee of the American Society for the Control of Cancer.—A symposium on communicable disease was presented before the Bergen County Medical Society at Bergen Pines, May 14, by Drs. Leverett D. Bristol, New York, speaking on poliomyelitis; Josephine B. Neal, New York, meningitis, and Philip M. Stimson, New York, recent developments in therapy.—Dr. James H. Means, Boston, addressed the section on medicine and pediatrics of the Academy of Medicine of Northern New Jersey, May 14, on "Some Endocrinopathies for Which We Have Successful Specific Treatment." Dr. Theodore Neustaetter, New York, addressed the section on obstetrics and gynecology, May 2, on "Present Day Status of the Value of the Endocrines in Sterility."—Drs. Charles Archie Crandell and Robert B. May, Greystone Park, addressed the Morris County Medical Society, Morris Plains, May 16, on "Alcohol and Its Relation to Mental Illness" and "Present Status of Shock Therapy" respectively.—Dr. Frederick D. Mott, Washington, D. C., and Mr. Harold L. Hoyt, New Brunswick, among others, addressed the Gloucester County Medical Society, Woodbury, May 16, on the Farm Security Medical Plan.

NEW YORK

Society News.—Dr. Frederick S. Wetherell, Syracuse, addressed the Onondaga County Medical Society, Syracuse, April 30, on "The Nodular (Adenomatous) Goiter—Medical or Surgical?"—Dr. Francis O. Harbach, Syracuse, addressed the Syracuse Academy of Medicine, May 21, on "Diagnosis and Management of Ovarian Dysfunction."—Dr. Ralph I. Lloyd, Brooklyn, addressed the Dutchess County Medical Society, Poughkeepsie, May 1, on "Proptosed Eye as a Diagnostic Problem."—Dr. Charles F. Branch, Boston, addressed the Medical Society of the County of Albany in Albany, April 24, on "Clinical and Pathological Aspects of Cholecystitis."—Dr. Norman H. Plummer, New York, addressed the Nassau County Medical Society, Garden City, April 30, on "Pneumonia: Diagnosis and Treatment."

New York City

Medical Administrator Wanted.—The department of hospitals of the city of New York has an opening as medical administrator to serve as deputy commissioner at a salary of \$6,500. The deputy commissioner is exempt under the charter from competitive civil service. Citizenship and three years' residence in New York are required. The candidate's technical knowledge and administrative experience will rate 50 per cent in consideration for the position and 50 per cent will be rated for personal attributes. All applications must be made in writing and should be addressed to the Department of Hospitals, 125 Worth Street.

Courses in Venereal Diseases.—Practicing physicians are invited to register for practical clinical courses of observation in venereal diseases, to be given under the auspices of the bureau of social hygiene of the city department of health, beginning June 10. Six sessions will be devoted to syphilis and six sessions to gonorrhea, each series of six meetings to be limited to six physicians. Emphasis will be placed on practical clinical matters. There will be no lectures and no certificates will be awarded. The sole purpose of the courses is to give the practicing physician an opportunity for first hand knowledge of modern diagnosis and treatment of venereal diseases.

Symposium on Arteriosclerosis.—A symposium on arteriosclerosis will be presented in the Erdmann Auditorium, New York Post-Graduate Medical School and Hospital, June 6. The program will be:

- Clive M. McCay, Ph.D., and Dr. John A. Saxton Jr., Effect of Retarded Growth on the Cardiovascular System and Other Systems in the Rat.
- Dr. James G. Carr, Chicago, Relation and Importance of Arteriosclerotic Disease in the Heart of Humans.
- Dr. Samuel Alcott Thompson, The Surgical Aspects for Treatment of Arteriosclerotic Heart Disease.
- Dr. Beverly Chew Smith, The Surgical Treatment of Arteriosclerosis Obliterans.
- Dr. Nelson W. Barker, Rochester, Minn., The Conservative Treatment of Arteriosclerosis Obliterans.

Society News.—Drs. John C. A. Gerster and Charles Gordon Heyd addressed the Medical Society of the County of Queens, April 30, on "Frozen Sleep Therapy in Cancer" and "Malignancy of the Large Bowel and Rectum" respectively. Dr. Robert L. Levy gave a Friday afternoon lecture before the

society, April 19, on "Diagnostic and Therapeutic Aspects of Cardiac Pain."—Drs. Richard H. Overholt, Brookline, Mass., and Samuel Potter Bartley, Brooklyn, addressed the Medical Society of the County of Kings, April 16, on "Clinical Studies in Primary Malignancy of the Lung" and "Reconstruction of the Arm and Hand" respectively.—Dr. Harold E. Himwich, Albany, addressed the New York Diabetes Association, April 19, on "Physiology of Insulin."—Drs. William DeWitt Andrus and Francis B. Berry addressed the Medical Society of the County of New York, April 22, on "The Importance of Vitamin K in Certain of the Hemorrhagic States" and "Surgery in Pulmonary Tuberculosis" respectively.

OHIO

Honored for Years of Practice.—The staff of the Fostoria City Hospital gave a dinner recently in honor of Dr. John H. Norris, marking his sixty-third anniversary of medical practice. He has practiced sixty years in Fostoria.—Dr. Mifflin B. Brady, Cincinnati, was recently honored at a dinner celebrating the fiftieth anniversary of his entrance into medical practice.

New X-Ray Unit Dedicated.—St. John's Hospital, Cleveland, dedicated a new million volt x-ray therapy unit and broke ground for a new \$2,000,000 nurses' home, recently. Speakers at the ceremony were Archbishop Joseph Schrembs, Cleveland; Dr. Max Cutler, director of the Chicago Tumor Institute, and Ernest E. Charlton, Ph.D., of the General Electric Research Laboratories, Schenectady, N. Y. The new unit is the second of its type, the first having been installed at Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York, in June 1939. It is of the gas insulated type, with the transformer tank and accessory apparatus installed on the first floor of the hospital in the space formerly occupied by a private room. Treatment ports through which the rays are directed at the treatment area extend into a treatment cubicle on the ground floor. Dr. David Steel is the roentgenologist of the hospital.

Society News.—Dr. Edward O. Harper, Cleveland, addressed the Portage County Medical Society, Kent, in April on "The Common Neuroses."—Drs. Roy L. Kile, Cincinnati, and Samuel Gendelman, Manchester, addressed the Adams County Medical Society, West Union, April 17, on "Precancerous Skin Conditions and Other Common Skin Lesions" and "Newer Uses of Sulfanilamide and Its Derivatives" respectively.—Dr. William B. Morrison, Columbus, discussed "Curability of Cancer of the Stomach" at a meeting of the Perry County Medical Society, New Lexington, April 18.—Dr. George L. Sackett, Cleveland, addressed the Tuscarawas County Medical Society, New Philadelphia, April 12, on "Errors in Roentgen Diagnosis."—At a meeting of the Auglaize County Medical Society in St. Marys, April 11, the speakers were Dr. Robert E. Boswell, Dayton, on "Clinical Significance of Hoarseness"; Dr. Robert Kent Finley, Dayton, "Infections of the Hand"; and Mr. James F. Conway, Cincinnati, "Professional Liability Insurance."

PENNSYLVANIA

Tuberculosis Society Election.—William W. Comfort, LL.D., president of Haverford College, Haverford, was elected president of the Pennsylvania Tuberculosis Society at its recent annual meeting in Williamsport, succeeding Dr. William Devitt, Allenwood. Dr. John J. Shaw, state secretary of health, Harrisburg, was named honorary vice president; Dr. Devitt and John H. Scheide, Titusville, vice presidents, and Dr. Charles Howard Marcy, Pittsburgh, secretary.

Society News.—Dr. Henry D. Lafferty, Philadelphia, addressed the Dauphin County Medical Society, May 7, on "Sudden Death Within Twenty-Four Hours After Delivery."—Dr. James H. Corwin, Washington, addressed the Washington County Medical Society, May 8, on treatment of fractures.—At a meeting of the Delaware County Medical Society, Chester, May 9, the speaker was Dr. Hugo Roesler, Philadelphia, on "Cardiac Diagnosis Without the Aid of Instruments."—Dr. Edmund R. McCluskey, Pittsburgh, addressed the Fayette County Medical Society, Uniontown, May 2, on "Laryngotracheobronchial Croup with Pulmonary Abscess."

Philadelphia

Alumni Reunion.—The alumni luncheon of the University of Pennsylvania at the University Club, May 15, was addressed by Dr. Alfred Newton Richards, professor of pharmacology at the school. His subject was "Research in Medicine at the University of Pennsylvania."

Schireson Sentenced to Eighteen Months in Penitentiary.—Dr. Henry Junius Schireson, a plastic surgeon, was sentenced, May 8, to two concurrent terms of eighteen months

in the Lewisburg Federal Penitentiary, according to the newspapers. He was permitted to remain at liberty on \$20,000 bail pending an appeal to the U. S. Circuit Court of Appeals. Schireson was convicted, March 27, of concealing \$130,000 in assets before filing in bankruptcy in 1937 and swearing a false oath. He was sentenced on both counts of the conviction. His bankruptcy petition listed assets of \$334 and debts of \$33,901. The \$130,000 he was said to have hidden from his creditors assertedly was transferred to his wife, it was stated. In urging a substantial sentence, Asst. U. S. Atty. Thomas J. Curtin said that Dr. Schireson pleaded guilty twice and was convicted once of selling narcotics illegally in Baltimore; served ten months in the Allegheny County Workhouse for conspiracy to cheat and defraud and six months in Rikers Island Prison, New York, for illegal practice of medicine. In 1930 Schireson's license to practice medicine in Illinois was revoked by the state department of registration after a hearing in Chicago on charges of malpractice. According to the report, Miss Sadye Holland, Chicago, testified that she went to Schireson to have a scar removed from her arm and that he induced her to undergo an operation to straighten her legs. Complications after the operation necessitated the amputation of both legs, it was stated. In 1933 the Illinois Supreme Court reversed the license revocation, holding that incompetent testimony was permitted at the hearing before the medical board.

SOUTH CAROLINA

State Medical Election.—Dr. George M. Truluck, Orangeburg, was named president-elect of the South Carolina Medical Association at its annual meeting in Charleston, April 30-May 2, and Dr. William L. Pressly, Due West, became president. Dr. Robert E. Seibels, Columbia, was elected vice president and Dr. Edgar A. Hines, Seneca, reelected secretary for the thirty-first year. The 1941 meeting will be in Greenville.

Special Society Meetings.—Dr. Richard B. Josey, Columbia, was elected president of the South Carolina Pediatric Association at the annual meeting in Columbia April 8. Dr. Wilburt C. Davison, Durham, N. C., was the guest speaker on "Pediatric Therapeutics."—The South Carolina Urological Association met in Columbia recently with Dr. Silas Raymond Thompson, Charlotte, N. C., as the guest speaker in the afternoon on "The Present Status of Prostatic Surgery" and Dr. Lloyd G. Lewis, Baltimore, in the evening on "The Neurological Bladder."

VIRGINIA

District Meeting.—The spring meeting of the Southwestern Virginia Medical Society was held in Radford, April 17. Drs. Isaac A. Bigger and William B. Porter, Richmond, conducted a round table discussion on "Infections, General and Local, from the Surgical and Medical Standpoint." At an evening session Dr. Walter C. Alvarez, Rochester, Minn., was the guest speaker on "Hints in the Treatment of Indigestion" and Dr. Harry W. Bachman, Bristol, presented a paper on "Fibroma of the Thyroid Gland."

WISCONSIN

Society News.—At a meeting of the Wood County Medical Society, Wisconsin Rapids, April 4, the speakers, all of Wisconsin Rapids, were Drs. Rogers E. Garrison on "Pulmonary Stenosis"; Wallace L. Nelson, "Pyelonephritis in Pregnancy," and Leland C. Pomainville, "Rocky Mountain Spotted Fever."—Dr. Ralph M. Waters, Madison, addressed the Brown-Kewaunee-Door Counties Medical Society, Green Bay, April 11, on "The Relation of Morbidity to Anesthesia."—The Milwaukee Society of Clinical Surgery was addressed at a dinner meeting at the University Club, May 28, by Drs. Harry Beckman on "Physiologic Aspects of Therapy"; Hugh A. Cunningham, "Clinical Indications for Oxygen Administration"; Ralph M. Waters, Madison, "Clinical Response to Oxygen Therapy," and Mr. James I. Banash, Chicago, "Mechanical Considerations of Oxygen Therapy Apparatus."

CANAL ZONE

Society News.—Dr. Clarence A. Mills, Cincinnati, addressed the Medical Association of the Isthmian Canal Zone at a recent meeting on "Climatic Influences over Combustion Level and Resistance to Infection." Dr. Mills also made plans for studies in tropical physiology to be carried out in cooperation with isthmian health agencies.

GENERAL

New Bulletin for Committee on Maternal Welfare.—The American Committee on Maternal Welfare is publishing a bulletin entitled *The Mother* to keep its members informed regarding its activities, to serve as a means of disseminating information on the plans and programs of maternal welfare which are being carried out in various communities. The first number appeared in April. It is not intended to be a medical journal or to present scientific articles. Offices of the committee on maternal welfare are at 650 Rush Street, Chicago.

Swindler of Physicians Now in Prison.—Oscar Hanson, Fort Worth, Texas, was recently incarcerated in the prison at East Lansing, Mich., following his apprehension for several swindles of physicians. Hanson's method was to buy glasses from oculists throughout the country, usually giving a check to the amount of \$30. He usually signed the name W. C. Curran in endorsing the checks, asking for the difference between the amount of the check and the price of the glasses in cash. He did not return for the glasses. When apprehended, Hanson admitted his guilt.

American Hospital in Paris Needs Funds.—An appeal has been issued for funds for the American Hospital in Paris by Winthrop W. Aldrich, chairman of the French and British Relief Funds. The hospital's facilities are being taxed to the utmost by the wounded soldiers and thousands of refugees. According to the announcement in the *New York Times*, the French and British Relief Funds, which have been aiding this hospital since the outbreak of the war, will at once send over all contributions that are given. Checks should be made out to the French and British Relief Funds and sent to their offices at 46 Cedar Street, New York.

Alumni Reunions in New York.—The annual luncheon of Phi Rho Sigma Fraternity will be held at the Hotel Belmont Plaza, New York, June 12, during the annual session of the American Medical Association. Alumni of Jefferson Medical College will hold a dinner at the Hotel Murray Hill, June 12. Dr. Thomas F. Duhigg is chairman of arrangements. He may be addressed at the hotel. Alumni of Northwestern University Medical School, Chicago, will hold a dinner at the Longchamps Restaurant, New York, June 12. Dr. Robert McGrath, New York, is chairman in charge. The Alpha Mu Pi Omega Medical Fraternity will hold a luncheon in New York at the University of Pennsylvania Club, June 12.

Human Serum Association.—The annual meeting of the American Human Serum Association will be held at the Willard Parker Hospital, New York, June 10. The following program will be presented:

- Drs. Maurice A. Hardgrove and Daniel B. Claudon, Milwaukee, Incidence of Syphilis Among Convalescent Serum Donors in Milwaukee.
- Drs. Aims C. McGuinness and Joseph Stokes Jr., Philadelphia, Use of Repeated Injections of Normal Pooled Serum in the Control of Upper Respiratory Infections.
- Drs. Paul J. Dwan and Erling S. Platou, Minneapolis, Bacteriostatic Properties of Scarlet Fever Convalescent Serum, Antitoxin and Hyperimmune Human Scarlet Fever Serum.
- Dr. William Thalheimer and Sophronia Myron, New York, Fate of Incompatible Iso-Agglutinins Which are Injected Intravenously.

A round table on blood substitutes will be conducted by Dr. Virgil H. Moon, Philadelphia; Dr. Sidney O. Levinson, Dr. Frank E. Rubovits Jr. and Dr. Heinrich Necheles, Chicago; Dr. Max M. Strumia, Bryn Mawr, Pa., and John Elliott, Salisbury, N. C. If time permits Dr. Stokes will introduce a round table on viruses.

Fellowships for Biological Research.—The Zoological Society of San Diego announces two scholarships available to advanced graduate students for research work at the Biological Research Institute on some phase of animal biology (concerned primarily with such branches as pathology, bacteriology, parasitology, physiology, comparative anatomy, comparative biochemistry, animal nutrition or animal psychology). The stipend of each scholar is \$1,000 annually. Since the institute is not directly affiliated with any university, it is desirable that the recipient of the scholarship work under the direction of the department from which he applies, and preference will be given to postdoctorate investigators or to candidates for an advanced degree, it being understood that only the thesis or dissertation requirements or parts thereof can be fulfilled at the Zoological Research Laboratory. Applications should be forwarded to Charles R. Schroeder, D.V.M., Zoological Society of San Diego, Balboa Park, San Diego, Calif., before June 15.

Chemical Society Awards.—Eric G. Ball, Ph.D., associate in medicine, Johns Hopkins University School of Medicine, Baltimore, received the Eli Lilly Award of \$1,000 for research in biologic chemistry at the spring meeting of the American Chemical Society in Cincinnati, April 8. Dr. Ball reported the discovery that riboflavin is a constituent of the enzyme xanthine oxidase. A native of England, Dr. Ball is 36 years old and took the degree of doctor of philosophy in physiologic chemistry at the University of Pennsylvania in 1930. Mary E. Pennington, Ph.D., New York, a consultant and adviser on handling the transportation and storage of perishable foods, received the Francis P. Garvan gold medal presented through the chemical society for distinguished service to chemistry. Dr. Pennington was chief of the food research laboratory of the bureau of chemistry in the U. S. Department of Agriculture from 1908 to 1919 and was manager of research for a commercial firm before going into private work as a consultant.

Broncho-Esophagological Association.—The twenty-third annual meeting of the American Broncho-Esophagological Association will be held at the Waldorf-Astoria Hotel, New York, June 5, under the presidency of Dr. Lyman G. Richards, Boston. Among the speakers will be:

Dr. Clyde A. Heatly, Rochester, N. Y., *Surgical Management of Intracardiac Cardiospasm.*

Dr. Millard F. Arbuckle, St. Louis, *Bronchoscopic Treatment of Lung Abscess.*

Dr. Samuel J. Pearlman, Chicago, *Sarcocarcinoma of the Esophagus: Is There Such an Entity?*

Drs. Chevalier L. Jackson and George S. McReynolds Jr., Philadelphia, *Anesthesia for Peroral Endoscopy.*

Dr. Mervin C. Myerson, New York, *Bronchoscopy in Tuberculous Children.*

Dr. George R. Brighton, New York, *Laryngotracheobronchitis.*

Dr. Frances W. Davison, Danville, Pa., *Some Observations on the Control of Humidity and Temperature in Oxygen Tents.*

Dr. Hermann E. Bozer, Buffalo, *Collapse Without Clinical Signs of External Pressure.*

The New York members of the association will hold special clinical demonstrations at various hospitals in the city June 14.

Winners in Health Conservation Contest.—Winners in the annual city and rural health conservation contests conducted by the U. S. Chamber of Commerce in cooperation with the American Public Health Association were announced recently. These awards are made on the basis of the manner in which a community is meeting its health needs and are not necessarily made to the healthiest communities. The winners in the city contest were Milwaukee for cities of more than 500,000 population, Memphis for cities between 250,000 and 500,000, New Haven and Hartford, Conn., tied for cities between 100,000 and 250,000, Newton, Mass., for cities between 50,000 and 100,000, Greenwich, Conn., and Plainfield, N. J., tied for cities between 20,000 and 50,000, and Englewood, N. J., for cities under 20,000. Counties winning awards were Northeastern Division, Alger-Schoolcraft Health Unit, Michigan; Eastern Division, Fayette County, Ky.; Southeastern Division, Lauderdale County, Miss.; South Central Division, St. Mary's Parish, La., and Western Division, Wasco County, Ore. Special awards for maintaining their high standards went to Davidson County, Tenn.; El Paso County, Texas; Pike County, Miss.; Shawnee County, Kan., and Woodbury County, Iowa.

American Neisserian Medical Society.—The sixth annual session of the American Neisserian Medical Society will be held at the Shelton Hotel in New York, June 10-11, under the presidency of Dr. Nels A. Nelson, Boston. Included among the speakers will be:

Dr. Irwin I. Lubowe, New York, Larry Landau, B.S., and Daniel Miskin, Ph.D., *Veneral Disease Prophylaxis—An Ideal Prophylactic and Technic.*

Dr. William Ray Jones, Minneapolis, *Correlating the Micropathology and the Clinical Findings in Gonorrhea.*

Drs. John F. Mahoney, Cassius J. Van Slyke, and Rolla R. Wolcott, Staten Island, N. Y., *Sulfathiazole and Sulfamethylthiazole in the Treatment of Gonococcal Infection.*

Drs. Jacob Bernard Bernstine and George W. Bland, Philadelphia, *Gonorrhea Complicating Pregnancy.*

Dr. Eleanor Louise R. Westphal, Ruth L. Charles, A.B., and Dr. Charles M. Carpenter, Rochester, N. Y., *Development of Sulfapyridine-Fast Strains of Gonococcus.*

Dr. Wolfgang A. L. Casper, New York, *The Biochemistry of the Gonococcus and Its Practical Importance.*

Dr. Walter M. Brunet, Chicago, *Is Gonorrhea a Bacteremia?*

Drs. Alfred Cohn, Boris A. Kornblith, New York, and Arthur Steer, Brooklyn, *Observations on Untreated Patients with Gonococcal Infection and Those Receiving Chemotherapy.*

Dr. Max Leopold Brodny, Boston, *An Improved Rubber Sheath for the Prevention of Veneral Infection.*

Annual "Doctor's Day" Proposed.—Senator Bilbo of Mississippi on May 15 introduced into the U. S. Senate a joint resolution proposing that June 22 of each year be designated "Doctor's Day" in commemoration of "the great sacrifices and untiring efforts and devotion of the members of the

medical profession in performing their duty to humanity by caring for the sick and injured in times of individual need and during periods of pestilence, war and other disasters and catastrophes." By the resolution, which was referred to the Committee on the Library and has now been reported favorably, the President would be authorized and requested to issue a proclamation annually calling on officials of the government to display the United States flag on "Doctor's Day" and inviting the people of the country to observe the day in an appropriate manner. In a speech in the Senate urging the passage of the resolution, Senator Bilbo paid tribute to the achievements and services of physicians. He quoted a part of the Hippocratic Oath to express the philosophy of the ethical physician and cited instances of the devotion of the physician to his calling. He concluded his address with the following peroration:

It seems to me altogether fitting and simple poetic justice would seem to demand that this long belated recognition be conferred; that we should duly create and record, among the memorabilia of our great nation, a day of commemoration for the great cause the doctor represents. That the observance of Doctor's Day may become a part of the customs of our enlightened age, a day of observance for not only the people of this age but even unto posterity.

Mr. President and gentlemen of the Senate, permit me earnestly to urge the passage of this joint resolution so that at least one day in each and every year shall be dedicated to the doctor, humanity's greatest benefactor, and on that day may every citizen send a card, a telegram or a letter of love and appreciation; send him flowers or other appropriate tokens of love and friendship, or, better still, drop in at his office or his home and personally convey to him a message of esteem and gratitude.

Meeting of Neurologists.—The sixty-sixth annual meeting of the American Neurological Association will be held at the Westchester County Club, Rye, N. Y., June 6-8, under the presidency of Dr. Foster Kennedy, New York. Included among the many speakers will be:

Drs. Lewis J. Pollock and Isidore Finkelman, Chicago, *Changes in the Demarcation Current of Injured Muscle During Tetanus Produced by Stimulation with Induced Current.*

Dr. Louis Casamajor, Joseph Roy Smith, Ph.D., Dr. Kate C. Constable and Charles W. P. Walter, B.S., *Correlated Clinical and Electroencephalographic Findings in Children with Focal Convulsive Seizures.*

Drs. Eli Jefferson Browder and H. Russell Meyers, Brooklyn, *Comparative Pathophysiological Alterations Produced by Increased Intraventricular Pressure.*

Drs. Howard C. Naffziger and Robert B. Aird, San Francisco, *Prolonged Jugular Compression—A New Diagnostic Test of Neurological Value.*

Dr. Norman H. Jolliffe, New York, *Effects of Vitamin B Therapy in Paralysis Agitans.*

Drs. Harold G. Wolff, Alvin M. Cahan, and George A. Schumacher, New York, *Studies of Migraine: The Contrast of Vascular Mechanisms in Headache and Preheadache Phenomena.*

Dr. Walter E. Dandy, Baltimore, *Results Following Complete Extirpation of Acoustic Tumors by the Unilateral Approach.*

Drs. Tracy J. Putman, New York, and Hiram Houston Merritt, Boston, *The Chemistry of Anticonvulsant Substances.*

Association for the Surgery of Trauma.—The second annual session of the American Association for the Surgery of Trauma will be held at the Claridge Hotel, Atlantic City, N. J., June 7-8, under the presidency of Dr. Edgar L. Gilcreest, San Francisco. The speakers will include:

Dr. Philip H. Kreuscher, Chicago, *Treatment of Fresh Wounds.*

Drs. Fraser B. Gurd and Laurie H. McKim, Montreal, *Use of Bipp and Liquid Paraffin in the Treatment of Wounds.*

Dr. Samuel Potter Bartley, Brooklyn, *Reconstruction Surgery of the Hand.*

Dr. Donald M. Glover, Cleveland, *A Summary of Fifteen Years Experience with the Tannic Acid Treatment.*

Dr. Anatole Kolodny, New York, *Traction Paralysis of the Brachial Plexus.*

Dr. Louis G. Herrmann, Cincinnati, *Diagnosis and Treatment of Post-Traumatic Osteoporosis.*

Dr. Herbert H. Davis, Omaha, *The Possible Etiological Relationship Between a Single Trauma and Malignant Tumor.*

Dr. Edward A. Kitlowski, Baltimore, *Preservation of Tendon Function by the Use of Skin Flaps.*

Dr. Robert P. Dobbie, Buffalo, *Avulsion of Lower Biceps Tendon.*

Dr. LeRoy Long, Oklahoma City, *Bilateral, Independent Rupture of the Long Head of the Biceps Brachii.*

Dr. Nelson J. Howard, San Francisco, *Pathologic Changes Induced in Tendons Through Trauma and Their Accompanying Clinical Phenomena.*

Dr. Hubbard T. Buckner, Seattle, *Treatment of Fractures of the Upper End of the Tibia Involving the Knee Joint.*

Drs. Fenwick Beckman and John E. Sullivan, New York, *Some Observations on Fractures of Long Bones in Children.*

Dr. Clay Ray Murray, New York, *An Evaluation of the Operative Treatment of Fractures.*

Dr. Willis C. Campbell, Memphis, Tenn., *Fixation of the Only Graft by the Use of Vitallium Screws.*

Dr. Charles S. Venable, San Antonio, Texas, *The Application of Vitallium in Compound Fractures.*

Dr. Harry E. Mock, Chicago, *Trauma and Low Back Pain.*

Dr. John E. Raaf, Portland, Ore., *Treatment of Patients with Protruded Intervertebral Disks.*

Dr. Angus L. Cameron, Minot, N. D., *The Compatibility Factor in the Transfusion of Blood.*

Dr. Earl C. Padgett, Kansas City, Mo., *Early and Late Care of Severe Injuries of the Face and Jaws.*

Dr. William T. Coughlin, St. Louis, *Wounds Involving the Skeleton of the Face.*

LONDON

(From Our Regular Correspondent)

April 27, 1940.

The Revision of the British Pharmacopeia

The last issue of the British Pharmacopeia was published in 1932 and revision every ten years was intended, alternating with the decennial revision of the United States Pharmacopeia. The next pharmacopeia was to appear in 1941, five years after the eleventh revision of the United States Pharmacopeia, but owing to war conditions the authorities have changed their general policy, and it is now intended to delay publication of the new British Pharmacopeia, although the work of revision goes on. In a lecture to the Pharmaceutical Society Dr. C. H. Hampshire, secretary of the Pharmacopeia Commission, described the work, which has been going on steadily since 1936. For most of the committees it has reached a stage at which publication is possible. Already four reports have been published and others are in preparation, but everything is subject to reconsideration. The efficiency of the new British Pharmacopeia is to be increased by including standards and assays not only for crude drugs and chemicals but also for as many galenical preparations and compounded drugs as possible. Some of these are already described in the Codex of the Pharmaceutical Society. Substances which are the subjects of patents were not formerly described unless licenses to manufacture had been granted to a number of firms. The rule has now been adopted that certain substances may be included if the patents are due to expire within a few years.

The new organic chemicals include sulfanilamide, which is recommended as the best known of the sulfonamides free from patent complications. Mandelic acid and calcium mandalate are included, as are calcium levulate for giving calcium by injection. Parachlorometacresol, urethane, vanillin, beta-phenylisopropylamine and its sulfate, cyclopropane, pyridine-beta-carboxylic acid diethylamide and theophylline and ethylenediamine. Parachlorometacresol is included for its use as a bactericide in sterilizing solutions for injection and as a preservative in certain solutions. Because of the difficulties arising from using various names for ointments containing metallic mercury, it is recommended that the ointment of the current British Pharmacopeia containing 30 per cent should be continued with the synonym "mercury ointment" and that a diluted ointment containing 10 per cent and carrying the synonym "blue ointment" should be introduced with the note "When mercury ointment or mercurial ointment is prescribed or demanded, diluted ointment of mercury shall be supplied unless, on inquiry, it is ascertained that ointment of mercury is required."

The new inorganic chemicals proposed are calamine, bismuth subgallate, dried magnesium sulfate, dried sodium sulfate, potassium chloride and sodium metabisulfite (for use as an antioxidant in addition to solution of epinephrine hydrochloride and injection of procaine and epinephrine). Calamine is described as basic zinc carbonate colored with ferric oxide. The test on ignition excludes the form containing added zinc oxide.

The principal vitamin preparations recommended are standardized concentrated solutions of vitamin A and D, an oil standardized to contain vitamins A and D, halibut liver oil containing not less than 30,000 units of vitamin A per gram, and crystalline thiamine hydrochloride to replace the adsorbate of vitamin B. Added to the serologic group are biologically tested preparations of antitoxinum histolyticum, toxinum staphylococcium detoxicatum, toxinum tetanicum detoxicatum, vaccinum choleraicum,

vaccinum staphylococcium, insulinum protaminatum cum zinco and progesteronum. The regulations provide for the control of biologically tested preparations throughout the British Empire.

Medical Publishing and the War

The war so far has had little effect on the publication of medical books. New books and new editions show no falling off. On medical journals it has had a perceptible but not great effect. Like other periodicals, they have become smaller. This is mainly due to scarcity of paper (which may soon be rationed) and falling off in advertisements.

The *British Medical Journal* has dropped its eight-page key to medical literature, and the supplement (dealing with medical politics) is incorporated instead of being an inset. Immediately on the declaration of war the number of pages (text and advertisements) shrank from an average of 144 to 100. By way of compensation smaller type is now used in various sections of the *Journal*, notably correspondence, editorials and annotations, notes on books and obituaries. The number of original articles submitted fell off in the early weeks of the war but soon returned almost to normal, much exceeding the available space. The policy has been adopted of giving preference and priority to articles of topical value relating to military medicine, surgery, hygiene and administration. Local news has been cut down drastically. Only two journals have suspended publication for the duration of the war—the *Liverpool Medico-Chirurgical Journal* and the *Birmingham Medical Review*. The former is the organ of the Liverpool Medical Institution, meetings of which continue as usual. In spite of the large number of physicians on military service, the medical societies are holding their meetings much as usual.

The Food Situation

As previously stated in THE JOURNAL, there is plenty of food in the country and our imported supplies are coming in practically unhindered, thanks to the convoy system and command of the sea. Since imported supplies amount to two thirds of the normal food consumption, they use a large amount of shipping, some of which it is desired to divert to importation of munitions. Moreover, the convoy system increases the length of voyages and so reduces the amount of goods that can be carried in a given time. More food is therefore being grown in the country. Two million more acres are now under cultivation and in the towns allotments, where a man can in his spare time cultivate a large part of the vegetables required by his family, have been provided on a large scale.

Much attention is being given to dietetics, so that food can be used in the best and most economical way. There is great room for improvement. Ordinarily too much meat is eaten and other dietetic mistakes are made. A campaign of instruction is going on, with the backing of the government. The people are being told that their traditional Sunday dinner of roast beef and Yorkshire pudding might disappear without the nation suffering. In a series of lectures Dr. J. C. Drummond, professor of biochemistry, University of London, pointed out that "the Oslo health meal" (entire wheat bread, milk, salad and apple) had in English schools given better results as regards both the health and the development of the children than the usual dinner of meat and cooked vegetables. The working class housewife has been learning that whole wheat bread is better than white bread for her children. The last war taught us the value of scientific research with regard to food. The fine research machinery here is now all available to the government and is being used. Germany's home front collapsed in the last war not only because of shortage of food but because of failure to realize the importance of the newly discovered facts of nutrition. Professor Drummond regarded fats as unimportant if, instead, green vegetables and energy foods were taken. Their deprivation was a hardship purely for

psychologic reasons. Physiologically we could do without them. Professor Drummond appears to be alone in holding this view.

There has been some rise in food prices, but they have been kept low as regards bread and other essential foods by a government subsidy of \$250,000,000 per annum. In the last war subsidized foods rose in price by 133 per cent and unsubsidized foods by 284 per cent. A small book, "Feeding the People in Wartime," has been published by two agriculturists, Sir John Orr and D. M. Lubbock. They point out that there is some loss in converting milk into butter and cheese. The full value is obtained only by consuming it as liquid milk. Milk should be subsidized so as to bring the present level of consumption by the poor of a quarter of a pint daily up to two thirds of a pint, the level of the rich. The potato they regard as of special value for health. An acre of potatoes yields twice as much food as an acre of wheat. So the potato is the best insurance against food shortage. It should be subsidized for increased consumption. Consumption of potatoes in Britain is only half what it is in some other countries, such as Belgium and Germany.

Poliomyelitis Virus in Sewer Water

During the summer months of 1939, Stockholm had a poliomyelitis epidemic in which seventy cases were reported. Dr. Kling, director of the serotherapeutic institute of Stockholm, inoculated a number of monkeys with samples of the contents of the city's sewer waters. Repeated inoculation tests on these animals elicited positive reactions. He thus confirmed the observations of Paul, Trask and Culotta made at Charleston, S. C.; that viruses eliminated in fecal discharges may survive for a certain length of time in sewer waters.

Malingering

Disease simulation is one of the characteristics of war psychosis. It constantly changes its methods and its maladies. To the old devices found in all armies and at all times, and brought to a high degree of perfection among colonial troops, has been added the technic of malingering that has received its inspiration from recent medical discoveries. Icterus, for example, is induced by picric acid, 0.25 Gm. sufficing to color the tissues and the mucosa from eight to fifteen hours after ingestion. Repetition of the doses provokes symptoms of true catarrhal jaundice. It is not rare for a false icterus to be superimposed on a toxic icterus. However, disease simulation is met by improved methods of detection, such as that of detecting picric acid in the urine by the Kohn-Abrest reaction or picramic acid by Derrien's reaction. Albuminuria is simulated by taking white of egg just before the examination or by adroitly adding it to the urine at the time of the examination. In such cases, however, microscopic examinations fail to disclose the cytologic substances of nephritis. Furthermore, white of egg contains abundant and diversified flora that is easily discovered. In one case, reported by Maurice Perrin to a gathering of army surgeons, the dilution of white of egg was kept in a small rubber flask that could be easily concealed and used. Arrhythmia, tachycardia and auriculoventricular dissociations are induced by strong doses of caffeine of from 0.8 to 1.5 Gm. This is easily detected in the urine. Disease simulators have learned the thermogenic properties of nitrate derivatives of the benzene nucleus and use them to provoke fever. Paget reported a case of glycosuria due to the injection of 5 mg. of phlorhizin. Barbiturates have been employed to cause coma. Various chemical intoxications have been detected, whenever suspected, by close observation and repeated tests. Assumed deafness and blindness have been unmasked by specialized methods as well as induced abscesses, cutaneous ulcerations

due to common vesicant substances, voluntary mutilations and conjunctivitis. Nervous and mental simulations are the most difficult to uncover. Observation by itself does not suffice. It requires an infinite amount of patience and skill on the part of the physician to trap the offender. Often friendly counsels will prevent a recurrence of false representations.

Deaths

The decease of Pierre Marie has been reported. His work lay in the field of anatomopathologic and psychologic clinical research. He is regarded as probably the last representative of the school of Charcot.

Professor Weinberg of the Pasteur Institute and member of the Academy of Medicine is dead.

Life Expectancy After Amputation

Investigations made by the Hamburg orthopedist zur Verth of the life span of persons who lost a leg or an arm upset the view largely entertained that such persons do not live as long as persons possessed of all their limbs. His conclusions are based on a large observational material (60,000 living and 3,600 dead). Most of the amputations were performed between the nineteenth and forty-fourth year. Zur Verth collected data to show the number of those amputated who were dead thirteen years later and compared these data with the normal mortality rate at each given age (19-44). The results were surprising. The mortality rate of the amputated, computed for each age level, was 3.68 per cent as compared with the mortality rate of 5.98 per cent for the rest of the male population. Differentiated according to the site of amputation, amputation of the arm presented a 4.15 per cent, amputation of the leg a 3.51 per cent and amputation of the arm and leg a 3.89 per cent mortality. The same results were obtained from observations on all those amputated during the World War and not confined to the age levels of 19 to 44. Accordingly, the life span of those amputated is more favorable at all age levels than that of the general population.

Blood as Legal Evidence

In a former issue of THE JOURNAL (Nov. 11, 1939, p. 1824), an official decision was reported on the legal value of blood tests for paternity. In the meantime further conversations have been conducted with experts in the field of serology and heredity that led to the following results: "Determination of the blood group constitutes a suitable method of excluding the paternity of a certain person in certain cases. Objections advanced against hereditary transmission or on the basis of possible mutations and modifications do not limit this fact." By "certain cases" are meant those blood groupings that admit conclusions "with absolute certainty."

Heritability of Pernicious Anemia

M. Werner systematically examined fifty-seven consanguineous groups with 525 members anamnesticly, clinically and by laboratory tests. In 9 per cent of the groups a second case of pernicious anemia was discovered. This can no longer be regarded as purely accidental. Special attention was given to a prepernicious diathesis, such as the presence of subacidity, blood modifications, tendency to anemia, leukopenia or lymphocytosis, paresthesia and glossal changes. In 5 per cent of the group such a diathesis was found. A significant element was its appearance in 15 per cent of siblings and in only 1 per cent of the more distant relatives. It could not be determined whether this diathesis would evolve into true pernicious anemia or whether the condition is to be regarded as that of forms which had not attained their complete development. Neither

constitutional characteristics nor definite predispositions could be ascertained. The possibility, however, of a causal connection between pernicious anemia and essential hypochromemia cannot be denied, though confirmatory observations are lacking. Four cases suggested this connection. As a result of these studies it is assumed that pernicious anemia represents a dominant hereditary predisposition with relatively limited manifestations. Marriage, or the begetting of offspring, from the point of view of race hygiene, is to be discouraged in certain cases of pronounced or of double familial heredity. Persons who show a prepernicious diathesis should be treated with liver.

Deaths

Prof. Werner Spalteholz, anatomist, died at the age of 79. He spent his entire university life in Leipzig. His school atlas of human anatomy appeared in 1895 and was repeatedly revised. He invented the method of making human and animal substances transparent, a method used frequently in health hygiene exhibits and for classroom demonstrations.

Prof. Hans Ziemann died at the age of 74. He was a noted student of tropical diseases. His monograph on malaria and blackwater fever is well known. He discovered the causative agent of frambesia and also *Trypanosoma vivax*.

Prof. August Borchard died February 19 in his seventy-sixth year. Together with Schmieden he published a textbook on war surgery and subsequently with Garré a textbook on surgery, which passed through several editions. For many years he was editor of the *Zentralblatt für Chirurgie*.

Prof. K. B. Lehmann, hygienist, died in his eighty-second year. A pupil of Pettenkofer, he established himself at the University of Würzburg in 1887 and retired in 1932. His special interests, evidenced by numerous publications, lay in the physiology of nutrition, industrial hygiene and bacteriology.

BUENOS AIRES

(From Our Regular Correspondent)

April 13, 1940.

Nutrition in Spanish America

In accordance with the recommendations of the third International Conference on Nutrition, which met in Buenos Aires (THE JOURNAL, Feb. 3, 1940, p. 425), a new course of studies was inaugurated March 27 in the Instituto Nacional de la Nutrición of Buenos Aires. Dr. R. M. Ortiz, president of the Argentine Republic, and other dignitaries of the state attended the opening ceremonies. Dr. Ortiz has shown a special interest in national nutrition and was instrumental in creating scholarships to enable physicians of Spanish-American countries to continue their studies in the national institute of Buenos Aires. Several scholarship holders from Mexico, Brazil, Uruguay and Paraguay registered for the courses. Prof. Pedro Escudero, director of the institute, in the inaugural lecture pointed out that the natives, centuries ago, had extensive knowledge of cultivation of the soil, of plants and of the conservation of perishable foods. Their food was chiefly vegetarian. The speaker attributed the collapse of native civilizations in Peru and Mexico and the lack of vigorous resistance to the Spanish invaders to a vegetable diet with its impairment of physical and mental vigor. After the conquest, food conditions as well as social conditions became steadily worse for the natives. Escudero also analyzed the present conditions of nutrition in Argentina, Chile, Colombia, Ecuador, Mexico and Brazil. His conclusions were that the present day nutrition of more than 50 per cent of Latin American people was insufficient in quantity, excessive in carbohydrates and deficient in fats and proteins. Likewise the mineral and vitamin food levels were low. Hence the majority of people in Spanish America were chronically underfed and suffered the degenerative effects of pronounced protein deficiency. The solution of these problems, he said, was not to be sought in culinary

recipes and public kitchens but had to be attacked by governmental social welfare. However, expert advice and cooperation were needed through all the stages from food production to food consumption.

Osteopetrosis in Argentina

Osteopetrosis is endemic in Madras, British India, and known as dental fluorosis in children. In October 1938 it was discussed in the sessions of the international headquarters of public health in Paris, at which time H. T. Dean, dental surgeon of the U. S. Public Health Service, Dr. Frank McCallum of Australia and Dr. M. T. Morgan of the British Ministry of Health read papers. In Argentina cases of osteopetrosis are constantly observed in a central district of the country. Though not hazardous to life, it induces increasingly in the course of the years bone disturbances and ailments due to fluorine salts in the drinking water. Since also the ligaments and surrounding tissues are affected, the bones lose their flexibility and elasticity, giving rise to motor disturbances, diffused pains and symptoms that resemble arthritis and rheumatism and may lead to invalidism. Investigations conducted by Drs. Capizzano, Valotta and Megy disclosed roentgenologically skeletal osteopetrosis in a large number of persons. The chemical analysis of the fluorine content of the water confirmed the observations. The disease manifests itself about the twentieth year. Pains due to the disease occurred mostly in the vertebrae, shoulders and hips.

There are several ways of attacking the problem. Water testing more than 1.5 mg. per thousand fluorine content could be cautioned against. Without reflecting on the chemical methods employed to neutralize fluorine-bearing water, it seems imperative to seek water sources that contain only minimal amounts of fluorine. Nor can the sanitary aspects of the situation be separated from the social. There is danger that without proper education the population of these fertile zones may become panicky and leave. Incidentally, the towns in these zones have been in existence for only twenty or thirty years, so that data of the effects of fluorine salts in water after long continued use on cattle and agriculture are incomplete. The national department of public health has appointed a clinical-radiologic-chemical research commission and is awaiting financial appropriations to begin to function. The governor of the province in which the affected districts lie has taken an interest in the problem. The examination of recruits in one of these districts showed that 73 per cent of 1,300 young men had characteristic striated teeth.

Marriages

LOGAN EVERETT SAWYER, Durham, N. C., to Miss Winifred Lontz Maxwell in Clarksburg, W. Va., April 28.

GERHARD ECKMANN, Herrin, Ill., to Miss Sylvia Vilma Crosby at University City, Mo., May 5.

JAMES LEVI THOMSON, Lexington, Ky., to Miss Dorothy Mae Knowles of Woodard, N. C., May 15.

WILLARD CARTER GOODPASTURE, Chicago, to Miss Dorothy Ruth Bangs of Salina, Kan., May 4.

JOSEPH H. HUMPERT, Covington, Ky., to Miss Margaret Jane Leslie of Maysville, May 14.

GEORGE KNOX SPEARMAN, Anniston, Ala., to Miss Oleta Billingsley in Jasper, March 24.

WILLIAM GRAVES WOODIN, Dunkirk, N. Y., to Miss Barbara Mason of New York, May 18.

RALPH OLIN BOWDEN to Miss Margaret Blun, both of Savannah, Ga., May 3.

ROBERT KLEIN, Shanksville, Pa., to Miss Johanna Schwellb of Pittsburgh, May 2.

JEROME A. HILGER to Miss Helen Backer, both of St. Paul, January 20.

Deaths

Joshua Rosett • New York; University of Maryland School of Medicine, Baltimore, 1903; instructor, associate and assistant professor of neurology at Columbia University College of Physicians and Surgeons from 1919 to 1934 and since 1934 professor of neurology; member of the American Neurological Association and the Association for Research in Nervous and Mental Disease; served in the World War, during which time he was a member of the committee for public information and was sent to Russia with the American Expeditionary Forces; at various times a fellow of the Mount Sinai Hospital and the Montefiore Hospital, assistant attending neurologist to the Vanderbilt Clinic and Roosevelt Hospital, adjunct neurologist to the Neurological Institute; author of "Mechanism of Thought, Imagery and Hallucination" published in 1939, "Intercortical Systems of the Human Cerebrum" published in 1933 and many scientific works; aged 64; died, April 4, in Merida, Yucatan, Mexico, of carcinoma of the stomach.

Gorham Bacon, Yarmouth Port, Mass.; Bellevue Hospital Medical College, New York, 1878; member of the Massachusetts Medical Society; fellow of the American College of Surgeons; formerly professor of otology at the Columbia University College of Physicians and Surgeons; at one time aural surgeon to the New York Eye and Ear Infirmary; consulting otologist to the Roosevelt and Minturn hospitals, Hospital for Ruptured and Crippled, New York, and Vassar Brothers' Hospital, Poughkeepsie, N. Y.; author of "Manual of Otology"; aged 85; died, March 5.

Joseph Francis Geisinger • Richmond, Va.; University College of Medicine, Richmond, 1912; member of the Southern Surgical Association, the American Association of Genito-Urinary Surgeons and the American Urological Association; fellow of the American College of Surgeons; past president of the Virginia Urological Society; professor of clinical urology at the Medical College of Virginia; served during the World War; urologist to Stuart Circle Hospital; aged 56; died, April 15, of arteriosclerosis and dissecting aneurysm.

George Hall Conklin, Superior, Wis.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1888; member of the State Medical Society of Wisconsin; served during the World War; at one time health commissioner and county physician; formerly medical director and superintendent of the Middle River Sanatorium, Hawthorne; aged 73; died, March 10, in St. Mary's Hospital, of uremia, leukemia and pyelonephritis.

Simon Pendleton Kramer, Fort Thomas, Ky.; Medical College of Ohio, Cincinnati, 1888; at one time professor of clinical surgery at the University of Cincinnati College of Medicine; past president of the Academy of Medicine of Cincinnati; member of the American Neurological Association; veteran of the Spanish-American and World wars; surgeon to the Cincinnati Hospital from 1910 to 1925; aged 72; died, April 12, in the United States Marine Hospital, Baltimore.

John Burnworth Critchfield, Lock Haven, Pa.; Medico-Chirurgical College of Philadelphia, 1898; veteran of the Spanish-American and World wars; formerly member of the state legislature; for many years chief of the tuberculosis division of the state health department; member of the Medical Society of the State of Pennsylvania; aged 64; died, March 25.

Arthur H. Cleveland, Chadds Ford, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1889; Medico-Chirurgical College of Philadelphia, 1899; formerly emeritus professor of laryngology at the Medico-Chirurgical College of Philadelphia; at one time on the staff of the Presbyterian Hospital, Philadelphia; aged 75; died, March 26.

Gilbert Mombach • Cincinnati; Medical College of Ohio, Cincinnati, 1909; member of the Central Association of Obstetricians and Gynecologists; past president of the Cincinnati Obstetrical Society; aged 52; on the staff of the Jewish Hospital, where he died, April 9, of pneumococcal meningitis, type III, mastoiditis and labyrinthitis.

Leckinski Ware Spratling • Medical Director, Captain, U. S. Navy, retired, Waverly, Ala.; University of the City of New York Medical Department, 1890; entered the navy April 16, 1890, and retired March 12, 1921, on his own application after thirty years' service; fellow of the American College of Surgeons; aged 72; died, March 20.

John Peter Miller • Grand Forks, N. D.; Baltimore Medical College, 1906; past president of the North Dakota Academy of Ophthalmology and Otolaryngology; served during the

World War; on the staffs of the Deaconess Hospital and St. Michael's Hospital; aged 60; died, April 18, of coronary thrombosis.

John Allen Caruthers, Baton Rouge, La.; University of Texas School of Medicine, Galveston, 1899; fellow of the American College of Surgeons; aged 64; died, April 10, at the Baton Rouge General Hospital, of a fractured hip and arm due to a fall and cerebral hemorrhage and paralysis agitans.

Frederick Morell Houghtaling, Sandusky, Ohio; Baltimore Medical College, 1896; member of the Ohio State Medical Association; city and county health officer; served during the World War; aged 66; died, April 17, in the United States Marine Hospital, Cleveland, of cerebral hemorrhage.

Isaac Cuthbert Evans Jr., Columbus, Ga.; Medical College of Alabama, Mobile, 1899; formerly county physician, county health officer, city physician and health officer; on the staff of the Muscogee Tuberculosis Sanatorium; aged 67; died, April 19, of cerebral hemorrhage and arteriosclerosis.

Thomas F. Black • Providence, R. I.; College of Physicians and Surgeons, Baltimore, 1890; an Affiliate Fellow of the American Medical Association; formerly on the staffs of the Rhode Island Hospital and St. Joseph's Hospital; aged 76; died, April 2, of arteriosclerosis and heart disease.

Clayton James Hyslop, Chippewa Falls, Wis.; Northwestern University Medical School, Chicago, 1916; member of the State Medical Society of Wisconsin; served during the World War; aged 49; died, March 13, in St. Joseph's Hospital, of cirrhosis of the liver and diabetes mellitus.

William Samuel Knapheide, Quincy, Ill.; Chaddock School of Medicine, Quincy, 1889; Long Island College Hospital, Brooklyn, 1890; member of the Illinois State Medical Society; for many years on the staff of the Blessing Hospital; aged 74; died, April 8, of cerebral hemorrhage.

Presley Louis Pound, Wyandotte, Mich.; Tulane University of Louisiana School of Medicine, New Orleans, 1916; served during the World War; aged 47; died, April 1, in the Veterans Administration Facility, Dearborn, of hypertension, arteriosclerosis and myocarditis.

John Martin Elderdice, Salisbury, Md.; University of Maryland School of Medicine, Baltimore, 1905; served during the World War; aged 61; on the staff of the Peninsula General Hospital, where he died, April 10, of rheumatic cardiovascular disease.

George Adam Stover, South Boston, Va.; University College of Medicine, Richmond, 1900; member of the Medical Society of Virginia; past president and secretary of the Halifax County Medical Society; aged 66; died, April 6, of cerebral hemorrhage.

William M. Bogart • Stevenson, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1900; past president of the Jackson County Medical Society; aged 64; died, April 7, in the Barnes Hospital, St. Louis, of carcinoma of the lung.

Seth Hattery, Massillon, Ohio; Bellevue Hospital Medical College, New York, 1879; member of the Ohio State Medical Association; bank president; formerly member of the city council and board of health; aged 90; died, April 3, of arteriosclerosis.

George Bailey Goheen, Coalport, Pa.; Jefferson Medical College of Philadelphia, 1901; member of the Medical Society of the State of Pennsylvania; for many years member of the board of education; aged 67; died, March 23, of diabetes mellitus.

Julius Jesse Du Bose, Maplesville, Ala.; Atlanta Medical College, 1895; member of the Medical Association of the State of Alabama; aged 70; died, April 7, in the Baptist Hospital, Selma, of adenoma of the prostate and bronchopneumonia.

Milford M. Brubaker, Troy, Ohio; Eclectic Medical Institute, Cincinnati, 1896; member of the Ohio State Medical Association; aged 67; on the staff of the Stouder Memorial Hospital where he died, April 10, of coronary thrombosis.

Louis Francis Kelling • Lakefield, Minn.; St. Louis College of Physicians and Surgeons, 1898; veteran of the Spanish-American War; aged 65; died, April 6, of septic pulmonary embolism following extraction of abscessed teeth.

Walter Thomas Diver • Troy, N. Y.; Albany (N. Y.) Medical College, 1907; fellow of the American College of Surgeons; on the staff of the Troy Hospital; aged 56; died, April 8, in Miami, Fla., of coronary thrombosis.

Ruey O. Ford, Gaylord, Mich. (licensed in Michigan in 1900); member of the Michigan State Medical Society; aged 78; on staff of the Mercy Hospital, Grayling, where he died, March 30, of intestinal obstruction.

William Pinson Roberts, Dothan, Ala.; Memphis (Tenn.) Hospital Medical College, 1904; member of the Medical Association of the State of Alabama; on the staff of the Frasier-Ellis Hospital; aged 67; died, March 2.

Jesse M. Brooke, Peebles, Ohio; Starling Medical College, Columbus, 1896; member of the Ohio State Medical Association; aged 69; died, April 2, of acute dilatation of the heart following an acute gastro-enteritis.

Lewis Greenberg * New York; University and Bellevue Hospital Medical College, New York, 1916; on the staffs of the Beth Israel Hospital and the Hospital for Joint Diseases; aged 53; was found dead, March 10.

David Shuler Black, Columbia, S. C.; Memphis (Tenn.) Hospital Medical College, 1895; member of the South Carolina Medical Association; aged 68; died, April 1, of carcinoma of the lung and chronic nephritis.

Grace Hovey Griffin, Houston, Texas; University of Buffalo School of Medicine, 1917; formerly on the staff of the Rochester (N. Y.) State Hospital; aged 54; died, April 2, of chronic lymphatic leukemia.

Roy Irwin Curry, Mansfield, Ohio; Western Reserve University School of Medicine, Cleveland, 1922; member of the Ohio State Medical Association; aged 46; died suddenly, April 3, of coronary thrombosis.

Clyde D. Elder, Marietta, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1905; member of the Medical Association of Georgia; on the staff of the Marietta Hospital; aged 63; died, March 9.

Bond Stow, Crestwood, N. Y.; Chicago Medical College, 1889; at one time on the staff of the Metropolitan Hospital, New York; aged 75; died, March 28, in Washington, D. C., of coronary thrombosis.

Maurice A. Hoover, Grand Island, Neb.; Medical College of Indiana, Indianapolis, 1881; aged 81; died, March 4, in the Veterans Administration Facility, Lincoln, of arteriosclerosis and heart disease.

Peter Nicklaus Delus, Louisville, Ky.; Hospital College of Medicine, Louisville, 1899; veteran of the Spanish-American War; aged 63; died, April 7, in the United States Marine Hospital of uremia.

Richard M. Jones, Louisville, Ky.; University of Louisville Medical Department, 1893; member of the Kentucky State Medical Association; aged 70; died, April 1, of cerebral hemorrhage.

William Lippencott Woodruff, Saranac Lake, N. Y.; Medical College of Alabama, Mobile, 1896; aged 76; died, March 8, in the Saranac Lake General Hospital of bronchopneumonia.

Clarence V. Gilmore, Hickory, Miss.; Louisville (Ky.) Medical College, 1893; member of the Mississippi State Medical Association; aged 69; died, April 3, in Meridian of pneumonia.

George Albert Causey, Swifton, Ark.; Memphis (Tenn.) Hospital Medical College, 1900; member of the Arkansas Medical Society; served during the World War; aged 66; died, March 20.

James William Stockman, Red Cloud, Neb.; Hahnemann Medical College and Hospital, Chicago, 1903; aged 66; died, March 6, of cardiac asthma and dilatation of the descending aorta.

Lester Lance Lightner, Ideal, Ga.; Southern College of Medicine and Surgery, Atlanta, 1913; member of the Medical Association of Georgia; aged 57; died in April of pneumonia.

Robert Samuel Martin, San Francisco; Rush Medical College, Chicago, 1895; aged 77; died, March 13, in the Lane Hospital of bronchopneumonia, arteriosclerosis and nephritis.

John Kay, Perrin, Mo.; Northwestern Medical College, St. Joseph, 1893; at various times county health officer, county physician and county coroner; aged 70; died, March 15.

Otto B. Ilch, Hamburg, Mo.; Marion-Sims College of Medicine, St. Louis, 1898; served during the World War; formerly county coroner; aged 71; died, April 12, of carcinoma.

Arthur Furman Kraetzer * New York; Cornell University Medical College, New York, 1916; on the staff of the Knickerbocker Hospital; aged 48; was found dead, March 4.

Seldon William Cohn, Fulton, Ky.; Medico-Chirurgical College of Philadelphia, 1899; member of the Kentucky State Medical Association; aged 61; died, February 6.

Ellen Dell Dresser, Theresa, N. Y.; Hahnemann Medical College and Hospital, Chicago, 1888; aged 77; died, March 30, of carcinoma of the right breast and the liver.

Karl Herbert Hall, East St. Louis, Ill.; Atlanta (Ga.) College of Physicians and Surgeons, 1901; served during the World War; aged 62; died, April 14, of pneumonia.

Lois Leverett Nelson, Berkeley, Calif.; Cooper Medical College, San Francisco, 1890; aged 82; died, March 21, of coronary thrombosis and arteriosclerosis.

Bascom Hugh Birney, Burkes Garden, Va.; Rush Medical College, Chicago, 1886; aged 82; died, April 19, in Miami, Fla., of coronary occlusion and arteriosclerosis.

Autilio John D'Allema * Detroit; Wayne University College of Medicine, Detroit, 1937; aged 27; was found dead in April of carbon monoxide poisoning.

Edwin Leopold Rose, New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1895; aged 73; died, March 17.

Don A. Anderson, Indianapolis; Medical College of Indiana, Indianapolis, 1895; member of the Indiana State Medical Association; aged 67; died, March 17.

Frank Andrew Smith, Winnipeg, Man., Canada; Manitoba Medical College, Winnipeg, 1906; aged 58; died, April 11, in St. Joseph's Hospital of uremia.

General Marion Center, Campton, Ky. (licensed in Kentucky in 1894); member of the Kentucky State Medical Association; aged 77; died, March 5.

Charles Sidney Seely, Los Angeles; State University of Iowa College of Medicine, Iowa City, 1897; aged 62; died, March 18, of coronary embolus.

William T. Cameron, Mace, W. Va.; College of Physicians and Surgeons, Baltimore, 1889; aged 73; died, April 12, in Mill Creek of cerebral hemorrhage.

Edgar Forrester, Toronto, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1884; L.R.C.P., Edinburgh, Scotland, 1884; died, March 4.

Ernest Lynwood Blackmun * Stockton, Calif.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1901; aged 66; died, March 3.

THE VALIDITY OF RECORDS OF PRIVATE PATIENTS IN THE EVALUATION OF RESULTS OF TREATMENT

To the Editor:—In a special article entitled "The Drug Therapy of Epilepsy" in *THE JOURNAL*, April 6, page 1347, Dr. William G. Lennox makes suggestions tending to show that the "records" from which I obtained the data on which I based the conclusions of the efficacy of sodium bromide in preventing the seizures of patients suffering from epilepsy (Remissions of Attacks in Epilepsy Treated with Sodium Bromide, *THE JOURNAL*, Feb. 26, 1938, p. 632) "may be artificially optimistic." Dr. Lennox, I assume, meant that optimism born of the conclusions reached from my data was "artificial," since, as he estimates, the data were derived from a material which was not homogeneous but was loaded with mild cases. I quote his paragraph dealing with this suggestion:

Statistics concerning patients receiving active medical attention need to be studied with respect to their source. On the one hand the records of clinicians may be artificially optimistic. Thus Pollock in 1937 saw eighty-five patients whom he had treated with bromides for more than a year. Of these, thirty-nine (46 per cent) had been without seizures for a year or more. He must have been treating an unusually mild group, for 72 per cent of the eighty-five had a previous history of a remission lasting a year or more. Probably the surviving clientele of any physician is weighted with favorable cases, for epileptic patients are notorious shoppers. They know that time is the essence of help and quite properly refuse to be under the treatment of one physician year after year if they do not experience improvement. Also the greater his reputation (and his fees) the fewer the number who can afford to continue profitless treatment.

To meet the objection appearing further in his article that spontaneous remissions of a year or longer occur without apparent cause in about 20 per cent of patients (a statement the basis of which I would like to know), it is of interest to point out that, in the group referred to while under treatment by sodium bromide, eleven patients had had no convulsions for more than one year, ten for more than two years, four for more than three years, five for more than four years, one for more than five years, three for more than seven years and five for more than eight years when last seen in 1937.

To support his conclusion that I must have been treating an unusually mild group, Lennox cites the prolonged remissions lasting for a year or more in 72 per cent of the eighty-five cases treated with sodium bromide. Combining the thirty-nine cases already described in which terminal remissions were brought about with the group in which remissions lasting over a year were brought about and then for one reason or another an attack occurred, there were sixty-one cases (71.7 per cent). The remissions had lasted more than one year in seventeen cases, more than two years in twelve cases, more than three years in eight cases, more than four years in five cases, more than five years in three cases, more than six years in two cases, more than seven years in four cases, more than eight years in six cases, more than nine years in one case and more than ten years in three cases. Thus, in twenty-two cases in which seizures had been stopped by the use of sodium bromide for periods of from one to more than ten years, with a mean of more than three years, an attack occurred often because the patient had after a long period of freedom from attacks neglected his medication.

That patients do not continue ineffectual treatment is almost axiomatic, but before it can be held that the good results reported from my material were brought about because a large portion of the total number of patients whom I had treated had gone elsewhere because of the inefficiency of the treatment, leaving only a small number whom I had benefited, it must be shown, if one is comparing the efficacy of treatment by sodium

bromide with that of dilantin sodium, that only a small number of ineffectually treated patients leave the practices of Dr. Lennox and the other authors whose statistics he seems to accept without question, and that larger portions of effectively treated patients remain in their practices. To assume that when good results are obtained by the use of sodium bromide the material must be loaded with mild cases and that when successful results are obtained with dilantin sodium it is not so loaded seems to me to be illogical.

It is well known that in a consulting practice only a small portion of the total number of patients seen continue to be treated by the consultant. The majority are sent back to the physician who referred the patient.

During the year 1937, in the material on which I reported, there were only eleven patients whom I first saw that year and had been treated by me for less than a year. This would indicate that the accrual of patients to the number I would continuously treat was eleven for that year. Since a consultant's practice grows from year to year, I think it would be fair to judge this as representing a yearly accrual for the preceding ten years. In ten years I should have accrued a little over a hundred patients. It would appear, therefore, that not a very large proportion of the patients whom I would regularly treat had left my practice.

In the total group of ninety-six cases there were thirty-three in which the cause of the convulsive disorder was attributed to a disease or injury of the brain. I maintain that the group reported on represents a fair cross section of extramural cases treated by any physician in private practice.

There is little difference between the surviving clientele of a physician in private practice and that in an extramural clinic. In fact, in my experience patients attending the Montgomery Ward Clinics of Northwestern University Medical School change their allegiance far more frequently than do private patients.

In the clinic for epilepsy, usually numbering between 100 and 120 active cases, 127 new patients were admitted and 103 patients failed to return from 1937 to 1940. It cannot be said that the thirty-odd patients who leave the clinic yearly do so because their treatment is ineffectual. In 1937 thirty-eight patients who had withdrawn from the clinic during the preceding year were canvassed by the social service department: six patients had died and four could not be found; of the remaining twenty-eight, no further attacks had occurred in fourteen (50 per cent).

Results equal to or better than mine have been reported from the Clinic for Epilepsy of the Northwestern University Medical School by Stone and Arieff (Stone, T. T., and Arieff, A. J.: Remissions in Epileptic Patients Treated with Sodium Bromide in an Outpatient Clinic, *Arch. Neurol. & Psychiat.* 43:299 [Feb.] 1940). There were sixty patients who had been treated for more than a year with sodium bromide. In thirty-three cases (55 per cent), all attacks were stopped for a year or more in thirteen, for more than two years in nine, for more than three years in eight and for more than four, five and nine years in one each. In thirty-eight additional cases treated from six to twelve months, attacks had stopped for a period of six or more months in fourteen cases. Thus, of the ninety-eight cases treated for six months or longer, the convulsions had been stopped in forty-seven cases for more than six months (48 per cent).

If the material both in private practice and in extramural clinics is overloaded with mild cases, is it any less thus overloaded when the patients are treated by dilantin sodium than by sodium bromide? Would it not be wise to wait for a period of a few years and then, when only a few patients leave the practice of physicians and clinics because of the efficacy of dilantin sodium, attempt another guess as to the overloading of my material with mild cases?

Dr. Lennox rightly says that statistics concerning patients receiving active medical attention need to be studied with respect to their source. Would it not be fair at least to suggest that, although the greater the reputation (and the fees) of a physician the more likely would patients not continue profitless treatment, leaving behind the mild cases, nevertheless a physician of greater reputation, whatever his fees may be, might treat the patient and make observations of results more efficiently than some others? This does not imply that because Dr. Lennox mentions my name in the quoted paragraph I have identified myself with such a physician and hasten to say that my fees have never been known to frighten any one away.

LEWIS J. POLLOCK, M.D., Chicago.

LEAD AS A HAZARD

To the Editor:—Two months ago, in the January 20 issue of THE JOURNAL, you published an article by Drs. Rathmell and Smith to which I must take exception, particularly as it followed so soon after a paper by Dr. H. B. Williams in which also many experts doubt the diagnosis. In this article the child is supposed to have had acute lead poisoning due to only an infinitesimal quantity of lead obtained from orange juice put into an aluminum container. It seems to me unwise to give great publicity to a so-called established case of lead poisoning in a child who is said to have ingested less than 0.02 mg. of lead. Most persons ingest more than that every day in their drinking water, with absolutely no known deleterious effects. An analysis of the dishes was mentioned but no report on this was made, and it is obvious that no accusation can be made without that, particularly as aluminum dishes should contain practically no lead. Besides, lead does not usually give the acute symptoms ascribed to it in this article. One substance that I know of, namely antimony, may give gastrointestinal symptoms such as vomiting, but to incriminate an infinitesimal amount of lead without knowing whether antimony was present in the juice is distinctly unscientific.

I write this vigorous letter because too much publicity is being given to minor exposures to lead these days. This is particularly true with regard to lead taken by mouth, which is so much less toxic than inhaled lead. That lead may produce deleterious effects there can be no question, but there is no evidence that a small fraction of a milligram can produce the effects ascribed to it in this article.

JOSEPH C. AUB, M.D., Boston.

GLOVE DERMATITIS

To the Editor:—In THE JOURNAL, April 20, page 1523, appeared an article by Drs. Norwood and Evans on glove dermatitis, which I read with considerable interest. On Dec. 4, 1939, I saw a patient with the same type of vesiculation, exudation, crusting and scaling as that described by Norwood and Evans. This patient gave a history of contact with tetra-ethyl lead in gasoline while working in and around the oil fields near our city. It may be of interest that the rationale of my mode of therapy consisted of ultraviolet irradiation to the volar and dorsal surface of both hands for sixty seconds at daily intervals for five days. As a supplement, I used salicylic acid 2 per cent, phenol 1 per cent, and Saratoga and rose water ointment in sufficient quantity for a base. The use of white cotton gloves were advocated as mittens to retain the ointment.

The surprising feature was the response to this treatment and regimen. The patient was discharged December 11 as having made an uneventful recovery, after five exposures to ultraviolet radiation and the local ointment described.

CHARLES C. VERSTANDIG, M.D., Houston, Texas.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

REFRACTORY PERIOD AFTER TUBERCULIN TEST

To the Editor:—Could you give me references on the refractory period following the intradermal test for tuberculosis in cattle? Do the same principles hold good in man as in cattle when the latter are "plugged" just before the visit of the veterinarian?

G. H. Hoxie, M.D., Kansas City, Mo.

ANSWER.—The "plugging" or "doping" of cattle with tuberculin for fraudulent purposes came into being soon after it was learned by Gutman of Russia, Bang of Denmark and Pearson, Cotton and Russell of the United States that some animals extensively diseased with tuberculosis and in or approaching the terminal stage did not react to the tuberculin test. This was believed to be due to the fact that they were already saturated with the products of the tubercle bacillus. It was then learned that the subcutaneous administration of one or more large doses of tuberculin would have the same effect; that is, the animal would not react to the usual dose of tuberculin even though tuberculosis was present. Certain dishonest cattle dealers and importers saw that they might profit through buying tuberculous cattle at a low price, give them one or more large doses of tuberculin and sell them as nontuberculous at a high price. This practice was carried out extensively in Europe and the Americas. Dr. Charles H. Mayo, who purchased a herd of thirty-four thoroughbred cattle in the East was probably deceived in this manner. When he bought them he insisted that they be tested with tuberculin and none reacted. However, on the first testing after they had reached his farm sixteen reacted strongly to the test.

In the early part of this century the cattle breeders of Argentina were putting forth every effort to keep tuberculosis from their herds. They were willing to pay enormous prices for nontuberculin reactors imported from Europe. Dealers took advantage of this fact, bought tuberculous cattle in Europe and arranged to have large doses of tuberculin administered aboard ship. When animals arrived in Buenos Aires they were always kept in quarantine for forty days, after which they were officially tested with tuberculin. Nonveterinary inspectors were employed to guard them while under quarantine. However, detectives discovered that during the night these inspectors were administering large doses of tuberculin so that at the end of the forty day period of quarantine the animals would not react to the official test (*Am. Vet. Rev.* 32:170 [Nov.] 1907).

In this country "plugging" continued to be a serious practice (*ibid.* 35:386 [July] 1909). Many cattle breeders lost large sums of money this way. When it was learned what was actually happening, Malm discovered that the desensitization is not permanent (*Rev. gén. de méd. vét.*, 1903, p. 401). In fact, it persisted only a few weeks. Therefore veterinarians advocated that buyers purchase animals subject to the results of tuberculin tests administered a certain period (usually sixty days) after they had been received from the seller.

Hauptmann showed that, when small but constant doses of tuberculin are administered at intervals of approximately two months, sensitiveness of the tissues disappears after the second or third administration and does not reappear for from seven to ten months. However, by this method the time element was too great for dealers and importers.

Vallee (*Ann. d'Inst. Pasteur* 18:545, 1904) made a careful study of this phenomenon with the thought of discovering some way to outwit dishonest persons. The usual method of administering the tuberculin test consisted of, first, taking the animal's temperature to be sure that it was normal (the normal temperature of cattle is approximately 101.3 F.) and then to introduce subcutaneously 0.25 cc. of tuberculin. Beginning six hours later, the temperature of the animal was taken at least once every three hours over a period of from sixteen to twenty-four hours. If tuberculosis was present the temperature elevation began to appear in from six to ten hours but occasionally as late as from sixteen to eighteen hours. A rise of 2 degrees was considered to be a definite reaction. However, Vallee found that by administering a dose twice as large as usual, that is, 8 cc. of a 1:10 dilution of tuberculin for large animals and 4 cc. of this dilution for small animals, a definite temperature elevation occurred when tuberculosis was present much sooner in

"plugged" cattle than in others. Indeed, he began to take the temperature two hours after the test was administered and every two hours thereafter to about the fourteenth hour. Any animal whose temperature increased 1.5 degrees following the administration of tuberculin he regarded as tuberculous and any from 1.5 degrees down to 0.8 degree he considered suspicious.

Moussu, who first used the intradermal test for cattle, while Mantoux developed it for man, found that a subcutaneous injection of a massive dose of tuberculin at the time of or just before the administration of the intradermal test interfered considerably with the reaction of the latter.

In testing human beings with tuberculin it has long been known that, regardless of the method used, severe acute forms of tuberculosis, such as meningitis, pneumonia and miliary disease, as well as extensive and terminal stages of chronic tuberculosis, interfere with or actually render useless the tuberculin test; that is, with such large numbers of tubercle bacilli present in the body large quantities of tuberculo-protein are liberated and the tissues are desensitized. One may desensitize human tissues by graduated doses of tuberculin beginning with those so small as to produce no reaction and gradually increasing the dose until large amounts of tuberculin can be administered with no reaction. Obviously, in the latter part of this desensitization process the usual test dose of tuberculin meets no response on the part of the tissues. Indeed, Rich has done some valuable experimental work in desensitization in an attempt to remove the dangers of allergy when reinfections occur. Probably the administration of one or a few large doses of tuberculin would temporarily desensitize the tissues in man, as it does in animals. However, no well informed physician would take the risk of administering such doses to a human subject unless by further research an entirely safe method is devised.

CARDIAC DILATATION AND HYPERTROPHY IN ARTERIOVENOUS ANEURYSM

To the Editor:—Why is it that the heart responds by enlargement to the increased demands made on it, as in arteriovenous aneurysm? Is the biologic mechanism involved known?

Thomas I. O'Drain, M.D., Philadelphia.

ANSWER.—The causal relationship between arteriovenous aneurysm and cardiac damage was first demonstrated experimentally by Mont R. Reid (*Bull. Johns Hopkins Hosp.* 31:43 [Feb.] 1920) and since then numerous investigators in both the clinical and the experimental field have established that this is true. The heart of a patient with an arteriovenous fistula responds by dilatation at first and then hypertrophy, since there is an abnormal strain placed on the heart because of the short circuiting of the arterial blood into the venous channels. This increases the venous return to the heart and therefore the load that must be cared for by it. If the cardiac output per stroke is roughly 60 cc. and 20 cc. is lost directly into the venous circulation, the venous return will be proportionately greater and the heart will attempt to expel this increased amount, in accordance with Starling's law (Starling, E. A.: *Linacre Lecture "The Law of the Heart,"* London, 1918). This is accomplished by increased filling and hence dilatation of the heart. It has been estimated that of the enlargement of the heart in arteriovenous aneurysm from 75 to 95 per cent is dilatation, which is a quickly reversible process. If the dilatation is present long enough, hypertrophy ensues and is more slowly reversible.

To substantiate this theory of the hypertrophy of the heart further, experimental observations have been undertaken to determine how great the cardiac output is in such cases. Harrison, Dock and Holman (*Heart* 11:337 [Dec.] 1924) showed that in one of their experimental subjects the cardiac output rose 100 per cent. Carter Smith (*Arch. Int. Med.* 48:187 [Aug.] 1931) found that the cardiac output of a patient with an arteriovenous fistula decreased 58 per cent following closure of the opening. Absolute results of the determination of the cardiac output in such cases are not accurate, owing to the passage of a good portion of the blood (containing the determining substance used, such as acetylene) directly back into the venous system, but comparative results such as these are worth considering. The amount of increase in cardiac output is usually directly proportional to the caliber of the vessels involved, the size of the opening and the proximity to the heart. Emile Holman (*Arteriovenous Aneurysm*, Macmillan Company, New York, 1937) and others have reported an increase in the circulating blood volume in such cases, but Reid and McGuire (*Ann. Surg.* 108:643 [Oct.] 1938) failed to confirm these observations as occurring in cases in which cardiac enlargement but not congestive failure has developed.

Lewis and Drury (*Heart* 10:373, 1932) state that it is their opinion that the cause of the cardiac enlargement is due to an

impaired coronary blood flow as a result of the lowered diastolic pressure. Others, however, have shown that the coronary blood supply is decreased little if at all in such conditions. Since the work of the heart is increased, the lack of a corresponding increase in coronary flow leads to a relative coronary flow insufficiency and this factor aids in the development of dilatation and later hypertrophy of the heart.

To summarize, the main factor in the development of cardiac dilatation and its hypertrophy in arteriovenous aneurysm is the increase in the amount of blood that the heart has to pump. It follows, therefore, that the greater the increase in output the greater the attendant symptoms and heart failure and the more rapid their onset. However, the exact ultimate mechanism for hypertrophy in this or any other condition is not established, although increased work, relative anoxemia and dilatation are intimately linked in the process.

SWEAT AND BODY ODOR

To the Editor:—What are the qualitative and quantitative analyses of sweat of white persons and of Negroes? It is understood that some material is excreted by the Negro in the tropics that is repelling to insect life.

M.D., California.

ANSWER.—As far as is known there are no important qualitative or quantitative differences in the sweat of white persons and of Negroes. There have been no reports showing that the amount of salts or lactic acid, for example, are in any way different. To be sure there are some differences in odor of the sweat of Negroes and of white persons, but this is dependent, for the most part, on the fatty acids and oils present. These odoriferous substances are secreted for the most part by the apocrine glands. Most of these glands are situated in the axilla, with fewer of them present over the pubis and around the anus and the nipples. Most mammals show examples of skin glands excreting substances that have strong odors. Most observers believe that in man these substances are secreted largely by sweat glands. A few, however, ascribe these materials to secretions of the oil glands. In any event they impart to the individual sweat, whether they originally are secreted in the sweat itself or not, a distinctive odor, peculiar to each individual. In most mammals odors from secreted materials from the skin are increased during the breeding season. The same is true for man during periods of excitement.

Some people show a much greater tendency to be attacked by various insects such as the mosquito. It is not entirely known just why there is this difference of attraction for insects by the skin of different persons. It is probable that the distinctive odors characteristic of the individual skin may have something to do with attracting or repelling insects. In a search of the literature nothing authentic on this point was found recorded. It is said that in the tropics white men are attacked more often by insects than are Negroes. It is further stated that after a certain stay there most white people become acclimated so that they become annoyed less often.

GONORRHEAL INFECTION AFTER MENOPAUSE

To the Editor:—A patient was infected with gonorrhea just past the menopause. She developed gonorrhea, endocervicitis, proctitis and infection of Skene's glands. I would appreciate your help in the treatment of this case as I am having difficulty in clearing the infection. M.D., Michigan.

ANSWER.—It is assumed from the difficulty in clearing up the infection that the condition is now in the chronic state. First the patient's general resistance should be built up and sexual stimulation and intercourse absolutely avoided. The use of alcohol should be forbidden. For pain, local heat or cold may be used or mild anodynes taken.

Local treatment should be simple and not excessive. Strong antiseptics usually are of no assistance and frequently do harm by causing extension of the disease above the internal os. The external genitalia should be kept clean. If there is a profuse cervical discharge it may be removed by means of hydrogen peroxide or a Luer syringe without a needle. Local applications of 2 per cent silver nitrate or 4 per cent mercurochrome are helpful but not curative. If the cervicitis is definitely of the chronic type, the best treatment is by means of some electrical apparatus, either the nasal tip cautery, electric coization or electrocoagulation. However, it is important not to cauterize the cervix too deeply or too high in the cervical canal.

The simplest treatment of infected Skene's glands consists of injection of silver nitrate, mercurochrome or other substance into each gland through its duct. For this purpose an ordinary Luer syringe may be used but the needle must have a dull tip and not a sharp point. If this treatment is unsatisfactory or

QUERIES AND MINOR NOTES

2239

not feasible, a better and more certain way is to use an electric current or high frequency current, which will nearly always destroy the glands and eradicate this source of infection.

Gonorrheal involvement of the rectum is more common than is believed. This condition may be treated by means of suppositories containing silver proteinate or mercurochrome, the suppositories to be inserted into the rectum after each bowel movement.

The instillation of acid capsules (No. 11 size containing 80 per cent β lactose and 20 per cent boric acid) into the vagina and acid douches (4 tablespoonfuls of vinegar [5 per cent U. S. P. acetic acid] to 2 quarts of water) may be beneficial.

Sulfanilamide may be helpful in this case. A satisfactory average dose is 2.6 Gm. (40 grains) daily, 0.65 Gm. (10 grains) after each meal and 0.65 Gm. at bedtime. Many patients have disagreeable and even dangerous symptoms from this drug, so great care must be exercised in using it. The size of the dose administered apparently has little to do with the toxic symptoms. Furthermore, rapid relief of symptoms following the use of sulfanilamide does not constitute a cure; hence slides and cultures must repeatedly be made for a long time following therapy.

numerous investigations and some controversy. Recently introduced methods of studying cutaneous disinfection quantitatively appear to have settled the question, showing that mercurochrome, in company with certain other mercurials, is not an efficient germicide when applied to the skin, although it does produce a more or less aseptic cutaneous surface because of the formation of a filmlike structure which covers over the bacterial flora that are present without much reduction. Consequently, neither aqueous nor alcoholic solutions of mercurochrome can be considered fully satisfactory or trustworthy in preparation of the field of operation.

Large quantities of mercurochrome continue to be manufactured and sold. The largest portion probably finds its way into private homes to be used on scratches, abrasions and cuts. Here, probably, lies its greatest field of usefulness. The best preparation for these minor injuries is an aqueous solution, at least 2 per cent, but preferably 3 or even 5 per cent. It should not be applied to suppurating wounds.

OBSITY

To the Editor:—Kindly advise me what I can do to reduce the weight of one of my patients. The patient is a single woman aged 36, a high school teacher; since having had scarlet fever at 15 years of age she has steadily gained in weight until she now weighs 230 pounds (104 Kg.), having gained 30 pounds (13.6 Kg.) since the first of this year. She is 5 feet 6 inches tall (168 cm.) and has not had a sickness since the scarlet fever, other than a slight cold now and then. Her menstrual history is negative. The blood Wassermann reaction is negative. She has been most cooperative in the matter of diet and I have had her on 1,000 calories and even down to 800 calories for weeks at a time; still she would gain and often become faint so it would be hard for her to do her work. I have given her one-half grain (0.03 Gm.) of thyroid twice daily combined with one-fourth grain (0.016 Gm.) of solution of posterior pituitary and perhaps she would take off a few pounds for a week or so, then remain the same for a time and then gain again slowly. Her blood pressure is usually 118 systolic, 80 diastolic, and the kidneys are normal.

ANSWER.—In order not to lose weight on an 800-1,000 calory intake, this patient would necessarily have a considerable depression of the metabolic rate. Since, from the description, there is no evidence of a decreased caloric expenditure, one is forced to the conclusion that the patient (unwittingly or deliberately) is deceiving herself and the inquirer with regard to the amount of food which she consumes. Hospitalization on a measured and supervised reduction diet is recommended. While it may be economically impracticable to hospitalize the patient for a long enough period to accomplish any considerable loss in weight, the procedure will at least give a standard for judging the efficacy of further efforts at treatment.

Howard M. Cooper, M.D., Rutherford, N. J.

MERCUROCHROME

To the Editor:—What is the present status or value of mercurochrome in modern surgery, when used either in minor lacerated wounds or on the skin previous to operating? I have looked through the journals for a few years past and find no satisfactory answer. Recently I was told that in some health talks to the public the speaker told the people in the audience that mercurochrome was not at all satisfactory as an antiseptic in wounds or on the skin, or any place.

ANSWER.—Few antiseptics have been given more extensive trial than mercurochrome. Introduced at a time when the need for better chemotherapy was felt acutely and when there were rivals in the field, mercurochrome has been used during the last two decades for almost every sort of local and systemic infection.

The more than 350 articles on mercurochrome which have appeared in literature deal chiefly with (a) results of intravenous injections for various local and general infections, (b) toxicity of the drug when so administered, (c) effects of local application for infections of skin, mucous membranes and external wounds, and (d) preoperative disinfection of the skin and mucous surfaces.

Intravenous therapy, already in disrepute, has been rendered obsolete by the introduction of sulfanilamide and related compounds. As for the value of mercurochrome in the local treatment of intractable infections such as eczema of the ears, pruritus, chronic cervicitis and ringworm, no final answer can be given at present. But since the drug has not been generally adopted for the treatment of such conditions, one may assume that it has not proved entirely satisfactory.

The merits of mercurochrome in preoperative disinfection of the skin and the mucous membranes have been the subject of

WOLFF-JUNGHAN'S TEST FOR PROTEIN DIGESTION

To the Editor:—Please inform me of the status and efficiency of Wolff-Junghan's test for protein digestion of the stomach. Is it useful in diagnosing carcinoma?

ANSWER.—This test is not in common use. It has been reported, however, as reliable for the estimation of soluble protein present in gastric contents. Its usage is based on the assumption that a gastric carcinoma secretes a peptic-splitting ferment that converts insoluble protein into soluble protein. Retained foods, saliva and bronchial secretions, as well as the presence of free hydrochloric acid, will give erroneous positive reactions. It may be used as a confirmatory test for gastric carcinoma if all these conditions are considered. Finally, the diagnosis of carcinoma is usually so evident at the time at which this test is positive that one does not have to resort to it for diagnosis.

Bruce N. Wolff, M.D., Gettysburg, Pa.

PREMATURE CONTRACTIONS

To the Editor:—Can a patient have premature contractions of the heart over a period of years and then fully recover? What is the likelihood of such disappearance and the probability of recurrence?

ANSWER.—It is perfectly possible for a person to have premature contractions for periods ranging from a few minutes up to many years without harm and with their subsequent complete disappearance. Recurrence may or may not take place, although such recurrence is common particularly if the premature beats have been numerous and long continued. More common, however, than the complete disappearance of premature beats themselves is the disappearance of the symptoms from them, particular the sense of palpitation. About half the persons who show premature beats on physical examination are unaware of their presence. Many individuals feel them at the beginning of an occurrence, for example the first few hours, days or weeks, and then, although the premature beats may continue, they may no longer be felt. Rare individuals are much troubled subjectively by their occurrence and often there is a cardiac neurosis involved.

H. T. Cuming, M.D., Pace, Miss.

CALCIUM AND TUBERCULOSIS

To the Editor:—Is not calcium administered in the treatment of tuberculosis for its anti-inflammatory effect, especially its check on exudation? Is it possible that calcium exercises a therapeutic anti-inflammatory effect during the first hours after administration and can this effect be prolonged by repeated taking (as practiced by many physicians)? Is literature available?

ANSWER.—The anti-inflammatory effect of calcium is uncertain and depends on conditions that are not fully understood. When administered intravenously, calcium chloride decreases the elimination of saline fluids by the intestine. It has been used considerably in intestinal tuberculosis, in some cases of which it decreases the diarrhea. Calcium phosphate and carbonate are often administered by mouth in cases of diarrhea, in which it is believed to serve as an antacid and to have a protective effect. The cathartic ions have been found to be antagonistic to calcium when saline cathartics are administered. It has also been found that calcium chloride relaxes longitudinal muscle and stimulates circular muscle of the intestine.

It is believed that calcium prevents pleural effusion, which may occur with lethal doses of thiosinamine and diphtheria toxin, and also the conjunctival inflammatory edema produced by oil of mustard. However, even this effect has been denied by some

M.D., New York

workers. Any effect which it has on peritoneal and pleural fluids is probably due to a decrease in the permeability of all the cells. In clinical serous effusions, calcium has not been found of value. This may be due to the fact that it decreases absorption more than the formation of fluid because of the decreased permeability of cells. It has also been found that calcium has a tendency to increase pulmonary and peritoneal transudation. Therefore the evidence concerning the value of calcium in the control of inflammations and exudations is not convincing. Apparently there has been no well controlled study in a sufficiently large number of cases to justify the belief that calcium is of any particular value in the treatment of the tuberculous patient who is on a normal diet, although in intestinal tuberculosis it may serve as a palliative measure.

COMPLETE AND PARTIAL EMPTYING OF BLADDER BY CATHETERIZATION

To the Editor:—A primipara aged 27 had fifteen hours of normal labor. Her blood pressure was perfectly normal, her kidneys did not show any change, there was no shock or hemorrhage, and she was delivered by a low forceps delivery. Twenty-four hours later the bladder became distended but the patient did not complain of discomfort, and the night nurse obtained 500 cc. of normal urine by catheter. The notes on the chart said that about half of the urine was removed. The next morning the physician commented on the chart that it was always better to remove all the urine in an obstetric patient with an acute retention. The surgical chief of the hospital objected strenuously to emptying the bladder completely and informed the nurses that it was not without danger. For my own curiosity I should like to know whether in acute retention in a normal healthy patient twenty-four hours following delivery it would be proper to withdraw the full amount to avoid a second catheterization. If you would be kind enough to decide this friendly debatable procedure, I would appreciate it.

G. C. Bates, M.D., Independence, Kan.

ANSWER:—There is no danger in the complete emptying of the bladder by means of catheterization in the puerperium. This is the usual procedure in most institutions. When the bladder has become overdistended by an acute retention of urine, its ability to empty completely should be demonstrated. Usually the patient is catheterized after voiding once or twice daily until the residual urine is less than 30 or 40 cc. The presence of a considerable residual urine in the bladder increases the hazard of urinary tract infections.

There may be some objection to the rapid emptying of the bladder of an elderly individual in whom there has been some urinary retention over a long period.

MILK FOR CHILDREN WITH FEVER

To the Editor:—Why do some physicians object to children taking milk when they have a slight elevation of temperature from a cold?

M.D., Pennsylvania.

ANSWER:—Certain physicians believe that, in acute febrile diseases or in colds with a slight elevation of temperature, the digestive functions may be impaired to some extent and that fat in the diet must be reduced and protein also held at a minimum. For this reason they may object to children taking milk during febrile diseases.

There is no scientific evidence to indicate that, during a cold with a slight elevation of temperature, such impairment of digestion occurs. Hence the rationale of limiting milk at these times is questionable.

DEAFNESS AND BLOCKING OF EUSTACHIAN TUBE

To the Editor:—A patient has recently brought to my attention an article written by Drs. T. Carroll Davis and John C. Rommell, of Philadelphia, in which they advise the use of prostigmine in cases of acute deafness associated with the blocking of the eustachian tube accompanied by ringing in the ears (known as tinnitus aurium). Would you please let me know what work has been done on this and if there is any physiologic basis for its use.

M.D., New York.

ANSWER:—Up to now there has been no confirmation of the results obtained by Davis and Rommell with prostigmine in acute deafness associated with blocking of the eustachian tube. This condition, however, is essentially a self-limited one which tends to clear itself up without any treatment and, if it does not, it usually responds readily to a few inflations. There is therefore some question whether or not the results reported were due to prostigmine or were due to the natural course of the disease.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, May 25, page 2143.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II, June 17-19. Part III, June or July, to be given in medical centers having five or more candidates desiring to take the examination. Exec. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: December 1940. In view of the small number of applications received before March 1, there will be no examination at New York, June 10-14. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: Written, October 21. Applications must be on file by September 1. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: General oral and pathologic examinations (Part II), (Group B) will be conducted in Atlantic City, N. J., June 7-10. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: Oral, New York, June 8-10; Cleveland, Oct. 5. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Oral and written, New Orleans, January 1941. Final date for filing application is November 15. Sec., Dr. Fremont A. Cl

AMERICAN BOARD OF k, June 3-5. Sec.

Dr. W. P. Wherry, 1500 e 10-11. Sec., Dr.

F. W. Hartman, Henry Ford Hospital, Detroit.

AMERICAN BOARD OF PEDIATRICS: Memphis, Tenn., Nov. 17, preceding the annual meeting of the American Academy of Pediatrics.

Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF RADIOLOGY: New York, June 7-10. Sec., Dr. Byrl R. Kirklin, 102-110 Second Ave., Rochester, Minn.

Arizona January Examination

Dr. J. H. Patterson, secretary, Arizona State Board of Medical Examiners, reports the written examination held at Phoenix, Jan. 2-3, 1940. The examination covered ten subjects and included 100 questions. An average of 75 per cent was required to pass. Five candidates were examined, all of whom passed. Three physicians were licensed by reciprocity and one physician was licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
Louisiana State University Medical Center.....	(1938)		1
University of Minnesota Medical School.....	(1939, 2)		2

Dermatologic Allergy: An Introduction in the Form of a Series of Lectures. By Marion B. Sulzberger, M.D., Assistant Clinical Professor of Dermatology and Syphilology, Skin and Cancer Unit of the New York Post Graduate Medical School and Hospital of Columbia University, New York. Cloth. Price, \$8.50. Pp. 540, with 52 illustrations. Springfield, Illinois, & Baltimore: Charles C. Thomas, Publisher, 1940.

The term "introduction" in the title of this book is unnecessarily modest. The reviewer knows of no work on this subject which approaches it in thoroughness, breadth of knowledge, clarity, scientific approach, and painstaking care to detail. Only one acquainted with the field of allergy and immunology, and especially its applications in dermatology, can realize what an emergence from an almost insoluble maze has been accomplished by Sulzberger in this book.

The presentation in lecture form is fortunate, as it allows the author the necessary freedom to present this difficult subject in a lucid, free manner, unhampered by the usual more formal methods. The language is clear. The highest standards for scientific discussions are met by this book. The marginal notes aid greatly in summarizing the material. The footnotes are excellent and in them the author cites his own opinions. In fact, throughout, the author never fails to state his own opinions on controversial matters, always, in addition, carefully presenting the views of others. Moreover, since he has been responsible for many of the important contributions in this field in recent years and for original studies made in this field in this subject, the book is replete with discussions of his own experiments, observations and conclusions, and their applications to clinical medicine. The bibliographies at the end of the chapters give the important articles, which in themselves summarize all the work. He also gives first publications on the subject (recognition so frequently neglected by many authors). Sulzberger's broad concept of allergy, together with its application in clinical medicine, is presented in detail, and its use in the diagnosis and treatment of dermatologic, infectious and medical conditions in general is clarified. All terms applicable to immunology and allergy are carefully defined. In addition the appended glossary of definitions is complete.

The first lecture is on definitions and classifications. The beginner will find this an excellent introduction to the subject of allergy. In lecture II, on some fundamental phenomena of allergy and their significance as common factors in certain diseases and reactions due either to nonliving allergens or to the agents of infectious diseases, the author discusses the fundamental principles of immunology and allergy in a lucid and instructive manner. Lecture IV, on the investigation of individual cases presumed to be based on allergy, presents all the necessary diagnostic criteria with emphasis on the necessity for intelligent criticism. The lectures on the necessity for the research worker and practical physician. The lectures on allergy in infectious diseases, tuberculin and tuberculodermis, especially well presented and complete. Here the author applies his broad concept of allergy to conditions not generally considered "allergic" in the narrow sense of the term. Lecture XIII, on allergy to drugs and on drug eruptions, presents one of the most important branches of this field. The experienced allergist and dermatologist knows how frequently drugs (mainly simple chemical substances) are the cause of remarkably varied and manifold complaints. This chapter offers the present knowledge on this subject in such a well organized manner that it should be of value not only to the specialist but to the practicing physician as well. In the concluding chapter, on the future of allergy, the author gives free play to his views and speculations for future investigative work. He discusses organ-specific antibodies, synergism, epithelial sensitization and prophylaxis. Any one who asks Is allergy here to stay? should read this lecture for the answer. In appendix I, Sulzberger has translated Pirquet's original article on allergy, which was published in 1906. Appendix II presents the most complete list ever published of substances used for patch tests and the concentrations employed. It is one of the most important of the practical contributions of this book. Appendix III presents the criteria for

determining the industrial character of a dermatitis. It is valuable to any one dealing with industrial medicine. Appendix IV, on the management of eczematous dermatitis and on the management of urticarial dermatoses, places in the hands of the physician the best accepted dermatologic local and general procedures used in these cases.

This book demonstrates that Sulzberger is a teacher as well as a tireless investigator. In addition to its great factual content, the style in which the book is written makes it enjoyable reading.

The Inter-Relationship of Mind and Body. The Proceedings of the Association, New York, December 27th and 28th, 1938. Editorial Board: Foster Kennedy, Angus M. Frantz and Clarence C. Hare. Association for Research in Nervous and Mental Disease, Vol. XIX of a Series of Research Publications. Cloth. Price, \$6. Pp. 381, with 28 illustrations. Baltimore: Williams & Wilkins Company, 1939.

One is first struck by the significant fact that this volume is only about half the size of recent volumes in this series and lastly by the even more significant fact that it could have been materially improved by a much greater reduction. This review is not concerned with the manner in which the various authors have presented their material. On the whole they have done as well as any similar group might have been expected to do. True they have attempted, unconsciously perhaps, to screen an enormous void of ignorance with a much fenestrated though thick curtain of words.

There is only one serious omission in the volume. There is nothing more than a passing reference (e. g. pp. 261, 307, 312) to the animal experimental studies of the influence of frustration and emotional stress on the activities of the remainder of the body. With the exception of this omission, the wordy volume can be accepted as setting forth fairly clearly the present state of our ignorance of the working of the mind. It is to be hoped that in years to come the volume will be frequently cited as evidence of the ignorance in this field in the first half of the twentieth century, just as the writings of Goltz and Brown-Séquard are now cited as evidence of the misunderstanding prevalent regarding cerebral localization in the latter half of the nineteenth century.

At no point is the purpose of the symposium which this volume represents made clear. From the material presented it is assumed that the aim was to present the existing knowledge concerning mental (and emotional) activity, the mechanism responsible for it and the effect of such activity on the rest of the organism. One can conclude from the book only that such knowledge is almost wholly lacking. That some of those who took part in the discussion were cognizant of this is evident (see pp. 1, 97) but one might have wished for a more frank and less verbose admission of that fact. Nor is it surprising that further progress has not been made when one surveys the unscientific manner in which information has been sought. Surely no worthwhile results are to be expected so long as we persist in the age old post hoc, ergo propter hoc type of reasoning. Yet, for example (and there are many others in this volume), there are set forth in chapters XVII and XIX, apparently for serious consideration, case histories in which a series of chronologically arranged events, selected according to the particular bias of the author, is presented as the cause of a particular neurosis and associated "somatic" disease. These discussions are completely lacking in appreciation for the need of accurate scientific controls. Yet such controls were available but were completely ignored. In case 1, pages 273-278, there were eight other siblings all of whom were born of the same "inconsiderate, domineering, self-centered, wilful" mother, who suffered from migraine, and the same "neat and clean" father, who suffered from an obsession, several of whom must have suffered from whooping cough as did the patient, must have had to take medicine administered by their mother, had discharging ears, been alive when siblings were born to their mother, and had dietary likes and dislikes, and so on ad nauseum. What of them? Did they, recipients of the same heredity and born into the same environment, also become sexually promiscuous, develop syphilis, a neurosis and asthma and die of periarthritis nodosa, cerebral hemorrhage and pneumonia? If not, why not? Surely such inadequate data cannot be accepted as establishing the primary importance of "an affection of the respiratory apparatus in early childhood," "emotional upsets" in

childhood and the "great dependence on, combined with hatred of, a domineering and aggressive mother" as primary causative factors in the development of asthma.

No intelligent physician would deny the primary etiologic importance of emotional and mental factors in some forms of disease. But if those factors are to be accurately assessed we must discard such superficial observations as these for a more searching study. We would agree with the statement of the psychoanalyst (p. 306) that "the spoken communications of the patient" are "no less valid therefore as the subject of scientific study than are visual data," but we would disagree with the psychoanalyst's apparent acceptance of these "spoken communications" as valid representations of the truth.

It is time that the entire medical and psychologic professions recognized an almost complete ignorance of the anatomy and physiology of the mind. It is not sufficient that we profess "that mental and emotional operations are more closely related to the activity of the brain than to that of any other organ" (p. 81), but essential that we either prove or disprove this statement by repeated and repeatable investigations carried out with strict observation of all relevant details and under exacting scientific controls. It is essential that we recognize or disprove that mental and emotional activities are not something occult and mysterious but are really nothing more or less than the manifestations of cerebral activity; that they are as surely cerebral physiology as is the study of the relation of the brain to the activity of skeletal muscle. If we are to comprehend the complex anatomic and physiologic facts of mental activity, complete advantage must be taken of animal experimentation with full recognition of its limitations, and serious scientific effort must be directed toward the study of these activities in the animal with which we are all primarily concerned, man. The clinical investigator must "experimentally set up stresses and strains upon the organism" (p. 305) and must take far more intelligent advantage of those situations which nature provides for him than he has in the past.

This book is one of the most distressing expressions of the ignorance of all of us that has come from the medical presses in many years. It can be recommended as a reasonably thorough documentation of that ignorance.

Leistungsfähigkeit und Arbeitselinsatz des Zuckerkranken: Eine Stellungnahme zum sozialen und arbeitswirtschaftlichen Problem des Diabetes mellitus auf Grund 8-jähriger Erfahrungen im "Ersten Deutschen Diabetikerheim" Garz auf Rügen. Von Dr. H. J. Banse und Dr. R. Splittkerheim. Mit einem Geleitwort von Prof. Dr. G. Katsch. Boards. Price, 6.30 marks. Pp. 95, with 8 illustrations. Leipzig: Georg Thieme, 1938.

A most interesting monograph on work capability of persons with diabetes has appeared appropriately enough from Germany. This paper, with an introduction by Professor Katsch, represents observations on the economic aspect of diabetes mellitus founded on eight years of experience in the First German Diabetic Sanatorium at Garz, on the island of Rügen.

The First German Diabetic Sanatorium at Garz has taken for its aim the training and schooling of the diabetic patient in order to return him to a normal productive life, i. e. to preserve his ability to work in spite of diabetes. Professor Katsch emphasizes the extreme importance of this work in Germany, quoting the words of the Führer that German working power is Germany's gold and adding that the "present shortage of workers here in Germany makes the productive diabetic treatment so important that it takes on the nature of a national duty for doctors to embrace it."

This masterly report stresses the favorable consequences to Germany's whole social economy of rehabilitation therapy which will permit thousands of sufferers to resume gainful occupations. It emphasizes the necessity for the supervision and training afforded by sanatorium treatment as at Garz whereby the diabetic patient can be trained to take full control of his regimen. Where such sanatorium treatment is unavailable, permanent help can be provided by the use of visiting nurses. Other sanatoriums have been built in Denmark and in Hungary modeled after that in Garz; and Italy is utilizing a system of visiting nurses.

After detailing the special equipment of which the sanatorium makes use, the report discusses the question of the insulin and diet requirement of the patient as a future worker in industry. The authors prefer the slow acting insulin. This is of special significance for patients who have to work, as the injections are

less frequent. They say "Sugar is used up mostly in the muscle cells. The diet treatment of the working diabetic must of necessity aim at the creation and preservation of sufficient oxidation material, and has, therefore, to look to a sufficient intake and use of sugar." Again, "Soon it was learned [at Garz] that work is therapy in many cases of diabetes." In other words, Germany, making a virtue of a necessity, is facing the problem of the rehabilitation of diabetic patients in a challenging fashion worthy of attention. This monograph is of sufficient importance to merit translation into English for those medical men who cannot profit from it in the original language.

Estudios fonocardiográficos y hemodinámicos en embarazadas y fetos en los últimos tiempos del embarazo normal. Por Julio C. Perelra. Tesis de doctorado en medicina. Trabajo realizado en el Instituto de fisiología de la Facultad de ciencias médicas de Córdoba (Argentina). Universidad nacional de Buenos Aires, Facultad de ciencias médicas, núm. 5103. Paper. Pp. 114, with 55 illustrations. Buenos Aires: Sebastián de Amorruutu e Hijos, 1939.

This thesis for a doctor's degree is divided into three parts. The first part describes the results of phonocardiographic studies of the heart of fifty pregnant and forty-nine nonpregnant women, arriving at the conclusion that no changes in the character or frequency of heart sounds attributable to gestation can be found. The second part gives a description of records of fetal heart sounds and furnishes data as to their duration, frequency, number of vibrations which form the first and second sound, and so on. In the third part the author discusses the hemodynamics in the fetus and in other periods of life, calculated on the basis of the aforementioned studies.

As to the technic, he prefers the direct method of recording heart sounds with Wiggers-Dean capsule and optical registration to the indirect, in which the sound is transformed into oscillations of an electric current and after a suitable amplification is registered photographically. He maintains that the results of the direct method correspond better to the acoustic perception by the physician's ears because in the electrical method certain frequencies are deliberately suppressed and others unduly amplified. Although he thus enters a controversial ground, his thesis furnishes many valuable data and demonstrates the slowly but steadily growing value of phonocardiography. The book will undoubtedly meet with a favorable reception in circles interested in the recording of heart sounds.

Thomson & Miles' Manual of Surgery. By Alexander Miles, M.D., LL.D., F.R.C.S., Consulting Surgeon, Royal Infirmary, Edinburgh, and the late Sir David Wilkie. Volume I: General. Volume II: Regional. Ninth edition. Cloth. Price, \$13.50 per set. Pp. 656, with 348 illustrations. 657-1371, with 644 illustrations. New York & London: Oxford University Press, 1939.

These two volumes, divided under the headings of regional and general, are concerned wholly with the clinical phases of surgery. The section on general surgery contains material on inflammation, repair, wounds and infections. Specific diseases such as syphilis, gonorrhea and tuberculosis, and diseases of systems such as vessels, nerves and bones are covered thoroughly in the first volume. The second volume contains the specific locale of the surgical disease with the anatomy, pathology and clinical features of the parts involved. The subjects are treated with a considerable detail and thoroughness throughout. It is doubtful whether in this country it is necessary to give such detailed methods of handling syphilis as are encountered in this surgical manual. The treatment of syphilis is not essentially a surgical problem, and doses of arsenicals and courses of treatment outlined in this book have been questioned in recent years.

The two volumes are treated as one unit, and each volume possesses a common index. While the contents are encyclopedic in character, clinical signs and symptoms are especially well portrayed. Preoperative and postoperative complications are discussed with surprising comprehensiveness. Recent advances in surgery are not particularly emphasized, although the last edition is dated 1931. No mention is made of the use of vitamin K in the preparation of jaundiced patients for surgery, a valuable therapeutic measure introduced over a year prior to the date of publication. Sulfapyridine is mentioned. The technical side of the surgical procedures is not dealt with in these books, and in general treatment is not always as satisfactorily portrayed as the diagnostic portions. This manual contains a great amount of well organized information and is especially valuable in the clinical phase of the practice of surgery.

A Symposium on the Blood and Blood-Forming Organs. Cloth. Price, \$3.50. Pp. 264, with illustrations. Madison: University of Wisconsin Press, 1939.

This is a collection of papers delivered at the Institute for Consideration of the Blood and Blood-Forming Organs, held under the auspices of the University of Wisconsin Medical School Sept. 4-6, 1939. The subject matter, which consists of both reviews and new observations, was presented by hematologists from several of the medical schools of the United States and included a paper on "Some Historical Aspects of Hematology" by Professor Meulengracht of Copenhagen. Watson's article on the porphyrins is a summary of the present knowledge of the formation, excretion and significance of these substances. Rhoad's article on "Aplastic Anemia" describes the studies made at the Rockefeller Institute Hospital and emphasizes the point that there are several types of this disease. Articles on iron deficiency (Heath), nutritional anemias (Minot), erythroblastic anemias (Diamond), pernicious anemia (Meulengracht), leukemia (Forkner), the reticulo-endothelial system (Doan), infectious mononucleosis (Downey) and polycythemia (Reznikoff) form comprehensive reviews of the data which are considered pertinent at present on these subjects. Krumhaar has an excellent evaluation of the present knowledge of Hodgkin's disease, well worth studying. Haden presents the theory of "critical volume" in explaining hemolysis. Furth has summarized the extensive work on leukemia carried on in his laboratory on mice. Osgood describes some of the newer data obtained by the method of "marrow culture." Eagle simplifies the subject of blood coagulation in a selective review of the literature. The book will be of considerable value and interest to those specializing in hematology, giving, in a compact form, material which was previously scattered in many journals and books.

A Textbook of X-Ray Diagnosis. By British Authors. Edited by S. Cochran Shanks, M.D., M.R.C.P., F.R.R., Radiologist, The Prince of Wales's General Hospital, London, Peter Kerley, M.D., M.R.C.P., F.R.R., Physician to the X-Ray Department, Westminster Hospital, London, and E. W. Twining, M.R.C.S., M.R.C.P., F.R.R., Radiologist, Royal Infirmary, Manchester. In Three Volumes. Volume III. Cloth. Price, £3 3s. Pp. 800, with 710 illustrations. London: H. K. Lewis & Co., Ltd., 1939.

The first two volumes of this reference work have already been reviewed. The third encompasses the remaining subjects not included in the earlier volumes. These are divided into five parts: the central nervous system; the sinuses, mastoids and labyrinth; the bones, joints and soft tissues; the teeth and jaws; the eyes, and finally a section on cineradiography by Reynolds. In the latter is presented an interesting review of this subject by a well known authority. Despite the sixteen authoritative contributors to this volume there are relatively few contradictions. The section on the central nervous system is well done and exhibits considerable detail. The American reader may be astonished at the attention paid to arterio-encephalography in contrast to the rather brief discussion of ruptured intervertebral disk, but aside from this the material is well balanced. The section on the radiology of the paranasal sinuses and mastoids is splendid and includes a consideration of technic. The teeth and jaws are discussed by H. M. Worth succinctly and completely; this is an unusually valuable portion of the book. The major effort of the volume is devoted to the bones and joints, almost all lesions being touched on, but all too briefly. In a textbook of this size one should be able to find more than a passing mention even of the rarer conditions, but this is unfortunately too often not true. The discussion of fractures and dislocations does not cover the field to any degree. There is an excellent chapter on the pathology of bone disease, and the correlation of pathology with the x-ray appearances is consistently discussed. The arrangement of the material is somewhat confusing, leading to some repetition. The illustrations, all in positive, except those on the teeth and jaws, are uniformly good; but for a book of these pretensions they are too few. For example, none of the common anatomic variations are illustrated by actual roentgenograms; such an important disease as rickets has only two. The roentgenogram selected to represent Ewing's tumor is a rather poor choice. On the whole, however, the illustrations are well chosen and, considering their limited number, illustrate well the conditions discussed. The format and printing are excellent, but the binding seems quite inadequate

for so large a book. The three volumes form the most elaborate and complete reference book on roentgen diagnosis in the English language. Despite some shortcomings they represent an invaluable addition not only to the library of the roentgenologist but to every physician who uses the x-rays for diagnosis.

Mental Health. Forest Ray Moulton, Editor. Paul O. Komora, Associate Editor. Publication of the American Association for the Advancement of Science, No. 9. Cloth. Price, \$3.50. Pp. 470, with illustrations. Lancaster, Pa.: Science Press, 1939.

With Walter L. Treadway as chairman of the publication committee, the American Association for the Advancement of Science presents the fourth symposium in the field of public health. Preceding symposiums were devoted to cancer, tuberculosis and leprosy, and syphilis. The U. S. Public Health Service, National Committee for Mental Hygiene and the Mental Hospital Survey Committee collaborated in organizing the symposium. Some forty-nine papers and formal invited discussions as well as informal discussion comprise this most comprehensive survey of the field of mental health. An introductory comment on the aims and scope of the symposium, by Thomas M. Rivers, is followed by five sections, the first of which, Orientation and Methods in Psychiatric Research, presents the diverse approaches to research in psychiatry. Sources of Mental Disease, the Economic Aspects of Mental Health, Physical and Cultural Environment in Relation to the Conservation of Mental Health, Mental Health Administration, and Professional and Technical Education in Relation to Mental Health are the succeeding general sections. The symposium concludes with a public address by Dr. C. McFie Campbell on Human Needs and Social Resources. This symposium is remarkably well organized and unusually complete. The student of problems of mental health is confronted with the unpleasant fact that always he is dealing with problems of multiple determination. He is well aware that the limitations of his own science are such as to enable him to envisage quite incompletely only an aspect of the behaving personality. The present symposium is invaluable in aiding the student in any given field of study to orient himself as to his relationship to the general problem of human conduct. Doubtless, specialists in various given fields would feel that undue emphasis is given here, too little there; but there is no question that the symposium presents on the whole a well balanced survey. The difficulties scientists have in understanding one another's language and the degree to which the scientist may be distracted from his interest in man as man is perhaps best brought out by Dr. Edward Sapir's somewhat caustic discussion of Psychiatric and Cultural Pitfalls in the Business of Getting a Living. The papers maintain a high standard of excellence. The printed symposium should be at hand for every psychiatrist and for all serious students of human conduct and personal adjustment.

A Topographic Atlas for X-Ray Therapy. By Ira I. Kaplan, B.S., M.D., Director, Radiation Therapy Department, Bellevue Hospital, New York City, and Sidney Rubinfeld, B.S., M.D., Associate Visiting Radiation Therapist, Bellevue Hospital. Cloth. Price, \$4. Pp. 120, with 55 plates. Chicago: Year Book Publishers, Inc., 1939.

For successful radiation therapy, accurate representation of the diseased organ on the skin is a necessity. Carefully planned division and limitation of the fields are of the same importance as the thorough calculation of the dosage and of the amount of roentgens to be applied. The present atlas brings excellent illustrations of topographic anatomy as needed for proper settings in radiation therapy. Each drawing illustrates the organs to be treated and gives the relationship to their topographic landmarks as seen in projection on the skin. The exact placement of the cone completes the impressive illustration. Other photographs are added to show the lymphatic drainage of various organs most commonly affected in cancer which should be included in radiation therapy. In cases in which various methods of settings are used, as for instance in the treatment of carcinoma of the breast, the author illustrates various technics. The experienced authors did not fail to see that the position of the organs may vary in different individuals. Therefore they suggest that deviation from the standard anatomy be based on diagnostic x-ray examinations. Their work is valuable and helpful for safer and accurate radiation therapy.

Diabetes Mellitus and the Jewish Race. By Ernst Lyon, M.D. Paper. Pp. 32. Jerusalem: Ludwig Mayer, 1940.

This manuscript, which is more a compilation of the writings of others than the author's own work, is valuable in that it presents together the modern data on diabetes in Jews. According to Ernst Lyon, the Jewish race is not a pure race but has had many, many mixtures throughout all the years and therefore it is hardly correct to attribute the increase in diabetes in Jews to a racial origin. He emphasizes the necessity for the standardization of statistics because the Jewish population is older, owing to a smaller number of children. The possibilities of obesity and inbreeding must be considered. Furthermore, the social status and occupations are factors. The author is undoubtedly correct in stating that figures as to the incidence of diabetes in Jews must be interpreted according to their source. He says that those obtained from the private practice of specialists who are most frequently consulted by Jews with diabetes are of no (?) importance because the true number of the diabetic depends on the number and age of the Jews in the country. Lyon emphasizes the recent German statistics in which the mortality in Jews as compared with non-Jews in Germany was lower than had generally been considered, and he furthermore points out that Kahn estimated the Jews in Germany in 1936 to be 393,000, of whom 87,000 were over 60 years of age and half under 44 years of age, in contrast to the Jews in Palestine the same year, where the total was 395,000, of whom 17,000 were over 60 years and half of the total were under 20 years. Lyon also discussed the percentage of Jews among diabetic children. The reviewer knows of one group of 1,211 consecutive children in which the Jewish percentage is 6.6, whereas the percentage of Jews in a thousand cases of true diabetes investigated at the same time was 10.4.

Psychobiology and Psychiatry: A Textbook of Normal and Abnormal Human Behavior. By Wendell Muncie, M.D., Associate Professor of Psychiatry, Johns Hopkins University, Baltimore. With a foreword by Adolf Meyer, M.D., LL.D., Sc.D., Henry Phipps Professor of Psychiatry, Johns Hopkins University. Cloth. Price, \$8. Pp. 739, with 69 illustrations. St. Louis: C. V. Mosby Company, 1939.

Out of his extended experience in the Henry Phipps Psychiatric Clinic, the author has developed a new work on psychobiology and psychiatry which introduces several new features. The work follows essentially the methods of teaching used at the Johns Hopkins Medical School. After a historical introduction, several chapters are devoted to the student's personal study. Thus the student begins the course by making a personal study of himself which he endeavors to make as objective as possible. Thereafter comes a consideration of abnormal behavior according to the usual classifications, with a third part of the book devoted to treatment and the fourth part to a historical bibliography. The work is especially attractive because of the excellent case reports, which graphically demonstrate to the student the nature of psychologic disturbances. Available also are diagrammatic analyses in the form of life charts of many of the patients. Modern psychiatry is in a developmental stage in which every author apparently requires special terminology for the elucidation of his classifications of mental disease. The historical bibliographic analysis, which occupies almost 200 pages of the book, seems to have been developed on the basis of a classification according to national contributions, with a special section for psychoanalytic contributions. This seems to be an extraordinarily wasteful method of presentation, the usefulness of which over a well written literary account is not apparent.

A Synopsis of Surgical Anatomy. By Alexander Lee McGregor, M.Ch., F.R.C.S., Assistant Surgeon, Johannesburg General Hospital, Johannesburg, South Africa. With a foreword by Sir Harold J. Stiles, K.B.E., F.R.C.S. Fourth edition. Cloth. Price, \$6. Pp. 664, with 648 illustrations. Baltimore: William Wood & Company, 1939.

This small textbook of surgery is amazingly informative. Essentially it is divided into two parts, anatomy of the normal and anatomy of the abnormal. There are numerous simple illustrations which are schematic and readily grasped. It contains several tabular outlines of anatomic relationships and measurements. Bibliographic references are presented as footnotes. This is a genuinely refreshing book, highly commendable for ready anatomic review.

The Fundamentals of Internal Medicine. By Wallace Mason Yater, A.B., M.D., M.S., Professor of Medicine and Director of the Department of Medicine, Georgetown University School of Medicine, Washington, D. C. Second edition. Cloth. Price, \$9. Pp. 1,021, with 255 illustrations. New York & London: D. Appleton-Century Company, Inc., 1940.

The first edition of this book was reviewed in *THE JOURNAL*, Jan. 7, 1939, page 81. The author states in a prefatory note that this revision, made fifteen months after the first edition, includes numerous alterations and additions without material increase in the size. One of the most obvious additions concerns brief discussions of sulfanilamide and sulfapyridine therapy; it is obscure why the author has used the English "sulphanilamide" and "sulphapyridine" instead of the commonly accepted American spelling. The attempt to obtain brevity with sufficient completeness encounters great difficulties. In the light of existing knowledge today a chapter on gastritis, no matter how brief, should include at least some references to the use of the flexible gastroscope. In the reviewer's opinion, the advantages of including chapters on diseases of the skin, diseases of the ear and diseases of the eye in a textbook of internal medicine are insufficient to warrant the space, which might be better applied to expanding some of the discussions on subjects more commonly included in this field.

Illustrations of Regional Anatomy. By E. B. Jamieson, M.D., Senior Demonstrator and Lecturer, Anatomy Department, University, Edinburgh. Section VI: Upper Limb. Section VII: Lower Limb. Second edition. Loose-leaf. Price, \$2.50; \$3.50. 42 plates; 52 plates. Baltimore: William Wood & Company, 1939.

This completes the entire edition of these pleasing anatomic illustrations. The previously issued five sections have already been reviewed in *THE JOURNAL*. The limbs lend themselves readily to the diagrammatic portrayal used in the drawings, and the lavish use of color helps considerably in keeping the intricate structures separate. As with the remaining sections, these additional portions can be recommended without reservation to the student of gross anatomy. The axilla is especially well portrayed. The knee joint and its ligaments could be more clearly described. Again it should be pointed out that for the small format employed too many details are occasionally delineated; this does not detract considerably from these splendid manuals.

Medicolegal & Industrial Toxicology, Criminal Investigation, Occupational Diseases. By Henry J. Ellmann, Ph.D., Director of Physicians' Laboratory Service of Toledo, Ohio. Cloth. Price, \$3. Pp. 324. Philadelphia: Blakiston Company, 1940.

This book is disappointing in its content. The author has endeavored to cover too wide a field in too brief a space, with the result that much of the material is so sketchy as to have little value. Some of the inaccuracies are not free from possible harmful results. For instance (p. 222) "Carbon monoxide concentration in the air must exceed 15 parts 10,000 (1,500 p. p. m.) to produce possible serious results." This is a misleading and dangerous statement. The tentative standard of the American Standards Association for permissible range of concentrations is 100 parts per million for exposures not exceeding eight hours daily and 400 for exposures not exceeding a total of one hour daily. "An exposure of 700 to 1,000 p. p. m. will in three to four hours produce severe headache, muscular incoordination, weakness, vomiting and collapse. This reaction is adequately described as 'severe'" (quoted from the American Standards Association proposed standards, based on experiences of various studies and experiments). The chapters on industrial poisoning and occupational diseases are so abbreviated as to be of little use. The book cannot be recommended either for students or for workers in the field it aims to cover.

A Guide to Ophthalmic Operations. By J. Bruce Hamilton, M.B., Ch.M., D.O. Foreword by Sir James William Barrett, K.B.E., C.B., M.D. Cloth. Price, 10s. 6d. Pp. 201. London: H. K. Lewis & Co., Ltd., 1940.

This small volume is a radical departure from most surgical guides in that the procedures of the operation itself are entirely omitted but the preparation of the patient, instruments, drugs and dressings and the postoperative care is outlined for a great number of ocular operations. The author's preliminary training was gained in residencies at Melbourne and London, and his private practice has been conducted in Hobart, Australia; thus the outline is more readily usable to those with a similar background. Perhaps the portion of greatest interest, and this more especially to the embryo ophthalmologist, is that dealing

with the method of preparation of dressings, care and storage of sutures and their preparation, and the care and sterilization of instruments, droppers, gloves and radium needles, in all of which the student has little or no teaching. The drugs, their preparation and sterilization, being taken from the British Pharmacopeia, necessarily have a limited application for the American ophthalmologist. Instruments are indicated as illustrated in British catalogues for the most part. Diet and nursing care are stressed. The volume is of great practical value for the ophthalmic surgical nurse, the student and the surgical assistant as a general outline in the preparation for the many ocular surgical procedures.

Love Problems of Adolescence. By Oliver M. Butterfield, Ph.D. Cloth. Price, \$2.25. Pp. 212. New York: Emerson Books, Inc., 1939.

This book is interesting and a valuable addition to the already large volume of literature on this subject. It does not answer many of the questions which are raised, but this is doubtless a good thing, because these are questions that cannot be answered categorically and *en masse* but must be considered individually. The proper value of the book lies in the fact that it shows what these young people are thinking about and what questions they are asking one another and asking older persons who might be expected to answer them. It is a book that should be studied by parents, teachers and all young people. Physicians, ministers and social workers also should find it useful.

Surgical Diagnosis. By Stephen Power, M.S., F.R.C.S., Assistant Surgeon, London Homœopathic Hospital, London. Cloth. Price, \$4.50. Pp. 228, with 66 illustrations. Baltimore: William Wood & Company, 1939.

It is a difficult task to write a book on surgical diagnosis in little more than 200 pages, yet this the author has accomplished. Twenty-two short chapters cover the entire field of surgery not exhaustively, it is true, yet sufficiently to be of much help in making a direct and differential diagnosis of almost any average surgical condition. The material is accurate and simply presented. The book is attractively printed and has a number of line drawings and illustrations which enhance the value of the text.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Accident Insurance: Erysipelas Following Extraction of Hair an Accident.—The defendant insurance company issued a policy of accident insurance to Mangol whereby it promised to pay certain benefits if he sustained injury or death provided such was not caused by disease germs or any kind of infection, "excepting only septic infection of and through a visible wound caused directly and independently of all other causes by violent and accidental means." The insured extracted by means of tweezers a hair, or hairs, from the inside of his nose with resulting bleeding. He applied iodine and inserted cotton in his nose. The next day his nose and face became swollen. Two days later he called a physician who diagnosed his condition as erysipelas. The next morning he died from the erysipelas and terminal bronchopneumonia. On the refusal of the defendant company to pay the benefits promised, the insured's wife brought suit. From a judgment in favor of the plaintiff, the defendant appealed to the United States circuit court of appeals, seventh circuit.

It was agreed, based on reasonable medical certainty, that erysipelas is a septic infection which develops because of some break in the skin or mucous membrane, such as a wound, an abrasion or a scratch, and that a pulling of a hair or hairs out of a nostril which resulted in a slight hemorrhage would produce a visible opening in the skin or mucous membrane. There was uncontroverted medical testimony that the erysipelas might or could have been caused by bacteria entering the insured's system through that opening. The terminal bronchopneumonia was the end result which followed the erysipelas owing to the lowered resistance of the patient.

In the judgment of the appellate court the evidence was sufficient to support the trial court's finding that the insured had died from a septic infection of and through a visible wound caused directly and independently of all other means by his plucking a hair, or hairs, from his nose with tweezers. The court could not agree with the defendant's contention that, because the insured intended to remove the hair or hairs, knew that by so doing he would cause a wound and knew or should have known that such wounding would probably end in serious consequences, the wound had not been caused by accidental means but had been voluntarily caused by the insured. It was the opinion of the court, therefore, that the evidence adduced justified the trial court's further finding that the insured had sustained a visible wound caused directly and independently of all other causes by violent and accidental means. Since the law in effect in the state of Illinois was controlling in this case, the court relied for its decision on a rule of law enunciated in *United States Mutual Accident Ass'n v. Barry*, 131 U. S. 100, 9 S. Ct. 755, 33 L. Ed. 60, which had been approved by the Supreme Court and some of the appellate courts of Illinois, that if in the act which precedes an injury something unforeseen, unexpected or unusual occurs which produces the injury then that injury has resulted through accidental means. In effect the court held that if an act is performed with the intention of accomplishing a certain result, and if in the attempt to accomplish that result another result occurs which was unintended and unexpected and not the natural and probable consequence of the intended act, then it cannot be said as a matter of law that the unintended result was not effected by "accidental means."

Accordingly, the circuit court of appeals affirmed the judgment in favor of the plaintiff.—*Mangol v. Metropolitan Life Ins. Co.*, 103 F. (2d) 14.

Malpractice: Res Ipsa Loquitur; Necrosis Following Injection of Local Anesthetic.—Preparatory to performing a circumcision on the plaintiff, the defendant physician made several injections of a solution which he believed to be novocain, a local anesthetic. At the point of the first injection the plaintiff experienced a burning and stinging sensation, and a blister formed which burst. The tissue in that area became necrotic, turned black and had to be excised. Later the plaintiff consulted another physician, who treated him for several weeks, but he was left "in such condition that he now at times suffers therefrom." He then brought suit for malpractice against the defendant physician. At the conclusion of the plaintiff's evidence, which consisted of testimony by himself and his wife, the trial court, on motion of the defendant physician, entered a judgment of nonsuit. From that judgment the plaintiff appealed to the Supreme Court of North Carolina.

The plaintiff did not allege that the defendant physician did not possess the requisite degree of learning, skill and ability necessary for the practice of his profession or that he failed to exert his best judgment in the treatment of the plaintiff's condition. Instead, he relied on the doctrine of *res ipsa loquitur*. He contended that the burning and stinging sensation which he experienced immediately after the first injection of the liquid and the destruction of tissue that followed was sufficient evidence to be submitted to the jury as tending to show (1) that the liquid injected was either novocain containing foreign caustic and deleterious chemicals or some liquid other than novocain that was caustic and deleterious, (2) that the liquid injected produced the condition complained of, and (3) that the defendant physician failed to diagnose properly the trouble and neglected to use proper treatment. But, said the Supreme Court, the doctrine of *res ipsa loquitur* is not applicable to this case. The plaintiff's testimony that the area to be operated on became "completely dead" following the injections only indicated that some type of anesthetic had been used. Was the burning and stinging sensation which followed the first injection due to some caustic chemical in the liquid or to some unusual and unexpected reaction of plaintiff's system to the medicine? Was the condition that followed the injection due to a caustic chemical in the liquid or to an infection? What was the defendant's diagnosis and what treatment should he have used? Did the second physician's diagnosis or treatment differ from that of the defendant? If the defendant incorrectly diagnosed the plaintiff's

condition and failed to apply the proper remedy, was this due to an error of judgment or to negligence? The answers to these questions, said the court, were not to be found in the plaintiff's evidence but were left to mere conjecture.

Practical application of medical science, continued the court, is necessarily experimental to a large degree. Owing to the varying conditions of human systems the result of the use of any medicine cannot be predicted with any degree of certainty. What is beneficial to many sometimes proves highly injurious to others. Even the expert cannot completely fathom or understand the reactions of the human system. To say then that an unexpected, unanticipated and unfavorable result of a treatment by a physician invokes the application of the doctrine of *res ipsa loquitur* would be to stretch that doctrine far beyond its real purpose. The court concluded, therefore, that the plaintiff had failed to offer any evidence tending to show that he had suffered any physical injury as a proximate result of any negligence on the part of the defendant.

Accordingly, the Supreme Court affirmed the trial court's judgment of nonsuit.—*Lippard v. Johnson (N. C.)*, 1 S. E. (2d) 889.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1930 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

*Pathogenesis of Bacterial Endocarditis. C. S. Keefer, Boston.—p. 352.

Pathogenesis of Bacterial Endocarditis.—The symptoms and signs of a chronic infection, the local signs of valvular heart disease, embolic phenomena and bacteremia suffice, according to Keefer, for the diagnosis of bacterial endocarditis. The diagnosis is often difficult when there is no bacteremia and when the disease is active but no signs of valvular disease are present. Bacterial endocarditis without bacteremia must be distinguished from acute rheumatic endocarditis and from valvular disease with infection elsewhere. The absence of bacteremia, lack of progressive nephritis and of signs of embolic phenomena, the presence of pericarditis and cardiac arrhythmias point to rheumatic fever rather than endocarditis. A previously damaged heart valve of rheumatic fever, the presence of platelet thrombi on the heart valves, transient bacteremia and the presence of antibodies are all important in determining the development of bacterial endocarditis. Bacterial endocarditis is most commonly encountered following rheumatic fever or congenital heart disease. The most vulnerable persons are those in good health, comparatively free from symptoms suggesting heart failure and who have not had repeated attacks of acute rheumatic fever. The disease is less frequent in patients with syphilitic aortic insufficiency than in patients with aortic valvular disease caused by rheumatic fever. It is rare in patients who have had attacks of heart failure or who have chronic auricular fibrillation. The common congenital defects which predispose to infection are congenitally bicuspid aortic valves and patency of the ductus arteriosus, although the infection occurs in connection with other defects. Deformed valves make a favorable place for bacteria to focalize and survive. Platelet thrombi on the valves serve as a favorable environment for the localization of infection. Nonbacterial thrombotic endocarditis occurs in a variety of conditions, and these platelet thrombi may become infected and produce bacterial endocarditis. Thrombotic and rheumatic endocarditis predispose to bacterial endocarditis because both afford a suitable area for bacteria to focalize and

gain a foothold, and, as such thrombi are relatively free of leukocytes, organisms focalizing here are able to survive. Since bacterial endocarditis always follows a bacteremia and its symptoms first assert themselves following extraction of teeth, tonsillectomy, respiratory infections or local infections with suppuration, it is imperative to discover the port of entry of the organism. Bacterial endocarditis may develop without a demonstrable preceding bacteremia, for nonhemolytic streptococci are normal inhabitants of the mouth and throat from a period shortly after birth until death. Experimental bacterial endocarditis in dogs, horses, rabbits and chickens suggests that damage of the valve, bacteremia and the presence of immune bodies all play a part in the pathogenesis of the disease. Platelet thrombi form on the heart valves shortly after they are ruptured and such thrombi serve as a suitable medium for the localization of bacteria. The situation is analogous to the conditions which favor the development of bacterial endocarditis in patients with previously damaged valves. Bacterial endocarditis has been produced experimentally by repeated intravenous injections of bacteria. An appreciation of the fact that the body possesses an immune mechanism capable of clearing the blood of organisms emphasizes the futility of trying to treat this disease with vaccines, immune serum or blood transfusions. The difficulty of destroying the organisms lies in the fact that they are capable of surviving in vegetations. Their survival is made possible by the building up of a wall of fibrin in the vegetation. The wall of fibrin is a suitable medium for the growth of the organisms and it prevents the invasion of leukocytes. The possibilities for sterilizing the vegetations would appear to be (1) the actual destruction of vegetations by chemical agents or (2) the prevention of deposits of fibrin. If this can be accomplished, the patient should recover. Patients who recover from infection of the heart valves may die as a result of the damage (subacute and chronic glomerular nephritis, progressive anemia, embolism and splenomegaly) that has been inflicted during the active, infective stage of the disease. There exists postmortem evidence of healed cases of bacterial endocarditis without any of the foregoing sequelae. It has been suggested that these are cases of bacterial endocarditis in which recovery occurred.

Hypoglycemic Reactions from Protamine Zinc Insulin.

—Lowrie and Foster observed eighty-nine persons who were given both protamine zinc and regular insulin. None were included in the study who had taken protamine zinc insulin for less than six months. Forty-three of the eighty-nine patients had no reactions from either type of insulin. Forty-two patients were subject to hypoglycemic reactions while taking regular insulin. Thirty-two patients had reactions after a change to protamine zinc insulin. Four patients who had been free from reactions on regular insulin complained of hypoglycemic symptoms with protamine zinc insulin. Of the twenty-eight patients having reactions from both forms of insulin, twenty-one observed less frequent reactions with pro-

tamine zinc insulin. Two patients had more frequent reactions with protamine zinc insulin. Decreased severity of reactions with protamine zinc insulin was noticed by nineteen patients. Four patients stated that hypoglycemic symptoms were more severe with protamine zinc insulin than with regular insulin. Insulin reactions were much more frequent in the under nourished. Of the thirty-two patients who were above normal weight, eight experienced reactions from regular insulin and only four from protamine zinc insulin. Reactions were encountered more frequently when higher doses of insulin were necessary for adequate control of the disease. Hyperglycemia in most patients could be controlled with a single daily injection of protamine zinc insulin and reactions in these patients were less frequent. Twenty-nine patients complained of nervousness, a sensation of trembling in the epigastric region and weakness. Twenty-three patients complained of hunger, twenty-one of sweating and blurring of vision, nineteen of headache and faintness, thirteen of somnolence and dizziness, eight of nausea, seven of paresthesias, six of disorientation and five of loss of consciousness. One patient has had two attacks of transitory hemiplegia. In changing from regular to protamine zinc insulin the following plan seemed to provide an interim free from hyperglycemia: On the first day four fifths of the total daily regular insulin dose is administered as protamine zinc insulin. If three doses of regular insulin are being used, the first two doses are given as usual but only half of the third dose. On the second day the same dose of protamine zinc insulin is given and the full first dose of regular insulin but the noon dose is halved and the last dose omitted. On the third day the same amount of protamine zinc insulin is administered; the breakfast dose of regular insulin is halved and the lunch and supper doses are omitted. On the fourth day protamine zinc insulin alone is administered. Readjustment of this dose may be necessary on subsequent days. Every new patient should be instructed not to disregard mild symptoms but to consider them as possible hypoglycemic manifestations. By proper education and strict supervision at the beginning of treatment much can be accomplished toward the prevention, early recognition and proper treatment of protamine zinc insulin reactions.

Tuberculosis in Medical Students and Young Physicians.—Hetherington and Israel secured information as to the incidence and course of tuberculosis of 98 per cent of the 400 physicians who had been examined as members of the classes graduating from the Medical School of the University of Pennsylvania in 1930, 1931 and 1932. Tuberculous infiltration of the lungs, in most instances asymptomatic, was found in about 18 per cent. Clinical tuberculosis requiring sanatorium care or collapse therapy developed within six to eight years after graduation in fifteen physicians, ten of whom had positive sputum. Two of the fifteen had had clinical tuberculosis in medical school before routine examination was instituted. Three physicians

had been negative on x-ray examination at graduation, while asymptomatic tuberculous lesions were discovered during the medical course in the remaining ten. Symptoms developed in the first two years after graduation in eight of the fifteen men. There was no recurrence of symptoms after graduation in three other men whose medical course had been interrupted by clinical tuberculosis requiring sanatorium care. The asymptomatic infiltrations found in 18 per cent of the 400 medical students consisted in more than a third of small, strandlike infiltrations. These lesions appeared to be chiefly of epidemiologic interest, but flocculent asymptomatic infiltrations, particularly when appearing below the clavicle, frequently resulted in clinical illness after graduation. Serious disease developed less often after graduation in students with lesions similar in character and extent in whom the diagnosis was manifest tuberculosis. This was probably due to the more radical restriction of activities and increase in rest advised. Absence of symptoms in students with extensive lesions, and the trivial character of symptoms described by students with minimal tuberculous lesions, indicated that definite ill health was rarely caused by tuberculous infiltrations until lesions became moderately advanced. Physicians who reported the development of clinical tuberculosis after graduation had moderately advanced or far advanced disease in every instance. Impairment of health sufficient to arouse suspicion of tuberculosis was thus apparently not noticed even by physicians while lesions were minimal. Asymptomatic tuberculous infiltrations progressed to clinical and fatal disease less often in medical students than in other groups more typical of the general population. This is attributed principally to the willingness of medical students and physicians to be treated when symptoms are slight or absent.

Bacteria in Air of Operating and Delivery Rooms.

MacDonald states that miscellaneous bacteria, including hemolytic staphylococci and alpha and beta hemolytic streptococci, were isolated from the air of operating and delivery rooms. The average number of organisms recovered from 10 cubic feet of air throughout the actual operating day was as follows: total number of bacteria 230,494, hemolytic staphylococci 3.49, alpha hemolytic streptococci 0.556, beta hemolytic streptococci 0.02. The Petri plate method of determining the bacterial content of the air under the conditions of the study gave results comparable to those obtained by the Wells air centrifuge. The extent of bacterial contamination in operating and delivery room air is influenced by the number of individuals and the amount of activity. The settling rate of droplet nuclei in these locations is such that there is no accumulation from day to day. The possibility of infection in clean operative wounds due to settling of droplet nuclei which contain hemolytic staphylococci and hemolytic streptococci must be recognized.

Air-Borne Beta Hemolytic Streptococci.—During the course of a scarlet fever epidemic in a maternity division of a hospital due to type III (Griffith) streptococcus, MacDonald studied thirty-two 10 cubic foot samples of air in an attempt to ascertain the extent of droplet nuclei transmission of organisms responsible for the epidemic. He found that, although hemolytic streptococci may be recovered from the air as droplet nuclei, the dilution is such that air-borne transmission of scarlet fever appears slight.

Sulfanilamide for Trachoma.—Spining administered sulfanilamide to fifteen adult patients with acute bulbar conjunctivitis with or without phlyctenules or corneal ulcers superimposed on a trachoma of long standing. The drug was

administered in daily doses of from 4 to 6 Gm. As soon as improvement was apparent, the dosage was decreased. All but one patient showed marked improvement of the acute symptoms in from three to four days, and in the majority photophobia, lacrimation, hyperemia and edema of the lids subsided entirely within three weeks. Corneal ulcers and phlyctenules cleared more slowly. Granulations of the palpebral conjunctivas and pannus, although improved, were always present at the time of discharge. Seventeen school children between the ages of 8 and 14 years, all having chronic trachoma diagnosed by an eye specialist, received doses of sulfanilamide suggested by Loe. In all of these cases trachoma had been present for a year or more. Clinically the cases were fairly uniform. Tearing, photophobia and bulbar conjunctivitis were definitely improved or had disappeared after three or four days of treatment. The conjunctivas of the lids became less congested and the granulations appeared paler and smaller. At the end of the treatment nine patients receiving sulfanilamide for from twenty-one to twenty-four days still presented granulations and velvet patches on the upper palpebral conjunctiva, and the pannus was still visible with the slit lamp. Only one of the seventeen cases could readily have been diagnosed as active trachoma at the end of treatment. In the author's opinion the results were no more striking than would be expected in similar cases hospitalized for the same period and given any of the usual forms of treatment. A check up of twelve of the children by an eye specialist three months after therapy was discontinued showed some improvement as compared to the condition of the eyes prior to the treatment. Considerable improvement was observed as compared with cases treated by other methods. However, there was no evidence of a complete cure or arrest of the trachomatous process.

Postmortem Chest Teleroentgenograms with Necropsy.—Hampton and Castleman made postero-anterior and lateral roentgenograms of the chest from the vertically suspended body after death at a distance of 7 feet. Postmortem roentgenograms corresponded to those taken ante mortem during quiet breathing or expiration. The differences in the antemortem and postmortem roentgenograms consisted of the degree of aeration of the lung and the alteration in the size and shape of the cardiovascular shadows. At necropsy the lungs were removed with the trachea, great care being taken not to tear the visceral pleura. Kaiserling solution No. 1 (a formaldehyde fixative) was instilled by gravity through the trachea until both lungs were approximately the size they were during life. The trachea was clamped and the specimen submerged in a large crock con-

taining the same fixative and allowed to remain for about a week. At the end of this period the lungs were sectioned by the pathologist in the presence of the roentgenologist. An attempt was made to find anatomic explanation for the shadows seen on the postmortem roentgenograms, and the roentgenologist attempted to find in the roentgenogram the lesions present in the specimen. The authors have studied 400 cases by this method. In the present study they were concerned with the recognition of pulmonary embolism and infarction. Use was made of a larger number of cases drawn from the 3,500 necropsies performed during the ten year period prior to the combined study. In this series pulmonary embolism and infarction were noted in 9 per cent of the cases, and in 3.5 per cent it was considered a major cause of death. In the combined study group of 400 cases, 14 per cent showed either pulmonary embolism or infarction, an apparent increase of more than 50 per cent. The authors emphasize the higher proportion among medical rather than surgical patients. Infarctions of the lung were found to be in contact with pleural surfaces, with the long axis of the infarct parallel to the longest pleural surface involved. The cardiac margin of the infarct is convex or "hump" shaped. Special attention is called to healing and healed infarcts. These produce linear shadows on the roentgenograms and are more easily recognized by the described method. The term "incomplete infarction" is suggested for the syndrome characterized by pleural pain or blood spitting or both, associated with a rapidly appearing and disappearing infarct-like area of consolidation in the lung without alveolar wall destruction. The authors conclude that there is often insufficient clinical evidence to allow a diagnosis of pulmonary infarction. There may be no pleural pain, blood spitting or an obvious source of embolism. In the presence of any one of these symptoms associated with x-ray evidence consistent with an infarct, the diagnosis may be made. In view of the fact that one third of the cases of pulmonary infarction is represented by patients who have not been operated on and who have no demonstrable cardiac lesion, it is important to consider pulmonary infarction in the differential diagnosis of pulmonary disease in ambulatory patients. An accurate diagnosis of pulmonary infarction is important in order that proper treatment may be instituted and fatal embolus prevented.

Radiation Therapy in Uterine Cancer.—According to Heyman, the Health Committee of the League of Nations decided in 1935 to issue annual reports on the uniform presentation of the results of radiation therapy in uterine cancer. The primary object of the proposed annual statistical reports was to provide a convenient reference work. In order to facilitate uniform presentation of data, the committee has adopted certain rules to be observed. "Notes for guidance of collaborators" specify the clinical types of cases to be reported, namely cancer of the uterine cervix, including cancer of the stump of the cervix. The following types are to be excluded: (1) cancer of the corpus uteri and vagina, (2) recurrences after radical operation, and (3) patients primarily submitted to combined operative and radiation treatment. The "notes for guidance" further specify that only cases microscopically diagnosed as cancer are reportable. Chorio-epithelioma, sarcoma, malignant mixed tumors and precancerous conditions are to be excluded. It is further stipulated that (1) the report is to relate to the total number of patients whose radiologic treatment was begun during the year to which the statement refers, as well as all patients examined with a view to treatment but not actually treated; (2) the statement is not to be completed until a period of observation of at least five years from the beginning of the treatment has expired in all cases included. The clinical material and the therapeutic results are to be presented in tabular form.

Arthritis and Para-Arthritis Treated with Roentgen Rays.—Weinberg has treated, since 1931, 160 cases of arthritis and other painful joint conditions with roentgen radiation. In the series were included arthritis, mainly of the hypertrophic variety, subdeltoid and subacromial bursitis, and cervical, dorsal and lumbar spondylitis. The predominant and often the only subjective symptom was pain of variable intensity and duration. Associated symptoms were limitation of motion, tenderness, swelling, in rare instances elevated temperature and malaise.

A large percentage of the patients had positive x-ray signs. The presence or absence of x-ray evidence of disease, however, was not considered a criterion in instituting the treatment. Radiation was given directly over the involved area. The dose was from 100 to 150 roentgens two or three times weekly and varied from three to twelve treatments. The factors were 180 kilovolts, 4 milliamperes, 0.5 mm. of copper plus 1 mm. of aluminum and 50 cm. focal skin distance; the fields varied from 10 by 10 cm. to 15 by 20 cm., depending on the size and the position of the involved area. The shorter the duration of the symptoms the sooner the condition was alleviated. The more chronic cases required a longer period to bring about satisfactory results. The large majority of the patients were completely relieved of pain and remained symptom free. Several patients had one or more recurrences and were relieved by a repeated course of treatment. A few did not respond to this therapy. A number of cases showed complete absorption of the calcified foci with disappearance of symptoms. The cases reported were referred by practicing physicians after they had, as a rule, exhausted other orthodox and standard types of treatment. The majority of the patients were followed up as long as five or six years. The author feels that the results obtained justify continuation of this form of therapy in para-arthritis associated with pain.

Oxygen Reactions Following Pneumothorax Refills.—

According to Pugsley, about 3 per cent of the tuberculous patients who have artificial pneumothorax at his institution are subject to a febrile reaction after each refill. The reaction (fever, malaise, chest pain, deep breathing, headache, general aches, nausea and/or vomiting) sets in about twelve hours after the refill and lasts for from twenty-four to forty-eight hours. When helium refills were given to same patients little or no reaction took place. Pneumothorax can be safely induced and maintained with helium, which appears to cause no irritation of the pleura. Refills slightly larger in amount than air are required to maintain the pneumothorax. Six patients subject to reactions after air refills had either slight or no reactions after helium refills. To determine the element in air which causes reactions the author gave nitrogen refills to each of the six patients, a mixture of helium and oxygen, and in three oxygen alone. No reaction followed the nitrogen refills, a slight or moderately severe reaction followed the mixture of helium and oxygen and a moderately severe reaction followed the oxygen refills. If a patient has a pneumothorax complicated by chronic tuberculous pleuritis, a refill containing oxygen may cause an acute febrile reaction of short duration which probably represents a flare-up of the tuberculous pleuritis. This observation supports the theory that oxygen supply is a vital factor in the activity of tuberculous foci and that the rich oxygen supply of the pulmonary parenchyma is a factor in determining the relatively low resistance of pulmonary tissue to the invasion of tubercle bacilli. In a case of tuberculous effusion an acute febrile reaction may follow aspiration of the fluid and air replacement. In such cases aspiration and nitrogen replacement should be tried. As nitrogen is less rapidly absorbed than helium, it is more suitable for refills.

Tuberculoma of Brain.—Buchstein and Adson report twelve microscopically verified cases of tuberculoma of the brain observed at the Mayo Clinic. Operation was performed in six. Tuberculosis of the brain is always secondary to a tuberculous focus elsewhere. The tubercle bacilli may reach the brain and its coverings by the growth of a contiguous lesion, they may pass from tuberculous lesions in the nasal and pharyngeal cavities to the cranial meninges by way of the perineural lymphatic channels accompanying some of the cranial nerves or, as is generally agreed, the great majority of tuberculous lesions of the brain arise by blood borne metastasis from foci which may be confined to one organ (usually the lungs) or may be generalized. Tuberculomas are divided into asymptomatic and those associated with clinical evidence of intracranial disease. Most instances of asymptomatic tuberculoma escape detection. Tuberculomas giving rise to associated symptoms of intracranial disease are divided into two groups. In the larger group the symptoms are exclusively or predominantly those of tuberculous

meningitis and the tuberculomas are more often small and multiple. There were four cases of this type in the authors' series. In two, in addition to the basilar meningitis, about thirty-five small tuberculomas of approximately equal size and similar structure lying in all parts of the brain were found. They had evidently resulted from a shower of tubercle bacilli in the blood stream. In the other two cases one and two small chronic tuberculomas of the cerebellum were observed. Tubercle bacilli were found in them only after prolonged search. In the other group (eight cases) the symptoms are attributable to the tuberculoma itself. They may be localizing in character or may be indicative of increased intracranial pressure. Tuberculomas producing symptoms of cerebral tumor occur at all ages and in persons who have but a single extracranial tuberculous focus, usually in the lungs or the associated lymph nodes. Tuberculomas associated with the clinical picture of meningitis occur predominantly in the early years of life and in association with generalized tuberculosis. The pathologic characteristics of tuberculomas are not different from those of tuberculosis elsewhere. Tuberculomas may be positively identified by finding acid-fast bacilli in them. The clinical syndromes which they produce are not significantly different from those produced by other varieties of cerebral tumor. A correct etiologic diagnosis is made only when the patient has active tuberculosis in another organ or in the presence of a positive tuberculin reaction in a child. A history of tuberculous disease in the past is suggestive but not conclusive. Laboratory studies do not aid in the differential diagnosis. The treatment of tuberculomas of the brain must be directed against tuberculosis as a disease and against the local lesion if possible. Attempts at removal of a cerebellar tuberculoma almost always end in disaster, owing to the development of tuberculous meningitis. Decompressive operations may afford relief until healing takes place. Fibrocaseous tuberculomas of the cerebrum and arachnoid tuberculomas, particularly those in the rolandic region, form the best subjects for surgical extirpation. Their symptoms permit of an early diagnosis and they are accessible to removal in one piece. Good results will follow in a gratifying percentage of cases.

Actinomycosis.—Morton points out that because actinomycosis is rarely diagnosed many cases are missed and an understanding of the disease lags far behind that of other chronic granulomas. Its bacteriology is complicated by the large number of organisms which have been described, only a few of them being pathogenic to man and none having any marked pathogenicity for laboratory animals. There is no generally accepted classification. Until a universally accepted bacteriologic classification is available clinicians will have to be content with the presence or absence of the ray fungus and call the disease "actinomycosis." The appropriate drug or vaccine will have to be determined in each individual case. The many forms of treatment testify to the inefficiency of any one type of therapy. Of the drugs, potassium iodide in moderate to large doses, i. e.

from 150 to 300 grains (9.7 to 19.5 Gm.) daily, is still the best therapy. Sulfanilamide used in two cases showed definite improvement in one but there was no observable effect in the other. This corresponds with other reports, and the conflicting accounts may perhaps be explained by peculiarities of the strain as well as by the concomitant infection present; e. g., in the first of the author's three cases, with a mixed infection with staphylococci, the drug had little or no effect, whereas in the third case, with an unusual strain of anaerobic Actinomyces, the improvement was appreciable. Surgical treatment is imperative in nearly all cases. When complete excision is possible it should be carried out; otherwise incision and drainage of all abscesses is indicated, combined with such other treatment as may seem best suited to the case. The prognosis varies with the site affected. In all suggestive cases early and diligent search for the ray fungus should be undertaken and a culture made from the material of the wall of the abscess when the pus is sterile.

Extrahepatic Biliary Tumors.—Henry emphasizes the frequent lack of diagnosis of jaundiced patients admitted to the hospital, and the frequency of obstructive jaundice due to carcinoma, especially that of the head of the pancreas. His studies include surgical specimens, biopsies and necropsies of the Central Division of the Montreal General Hospital for a period of ten years. There were 820 gallbladders removed and of these fifteen were removed for tumors of the extrahepatic biliary system. There were twenty-five women and thirty-five men with such diagnoses. The clinical records show fourteen patients in whom carcinoma of the gallbladder was diagnosed. There were thirty-eight patients with a diagnosis of carcinoma of the head of the pancreas with obstructive jaundice and three of carcinoma of the cystic, hepatic or common duct diagnosed at operation. The author believes that there occur each year five or six cases of obstructive jaundice due to carcinoma in the extrahepatic biliary system in the Central Division of the Montreal General Hospital. About 103 operations are performed annually on the biliary tract, making 6 per cent of these tumors extrahepatic. He concludes that the onset of painless jaundice in a person more than 50 years of age, with few exceptions, means carcinoma of the head of the pancreas. Pruritus frequently precedes jaundice in such cases. Repeated attacks of colic or of transient jaundice in a patient free from these for some years is suggestive of malignant change and calls for an exploratory operation. Operation on the gallbladder should be undertaken only by a surgeon who is prepared to deal with a tumor as well as with a stone. For obstructive jaundice due to a tumor in the lower ductal system which is not operable, cholecystogastrostomy appears to offer the patient the longest period of well being and freedom from cholemia. A hard mass at the head of the pancreas in a jaundiced patient may be a stone, even when thought otherwise by the operator. A fibrosing pancreatitis may simulate tumor and produce jaundice. Diabetes occurred but seldom in the sixty cases, while a mild hyperglycemia was a fairly common observation.

Hyperplastic Sinusitis in Allergic Patients.—Grove and Farrior report a bacteriologic study of 200 operative cases of chronic hyperplastic sinusitis. All the patients had some allergic manifestation. Four fifths had asthma. The other allergies were hay fever, vasomotor rhinitis, urticaria, angioneurotic edema, eczema, vernal catarrh and migraine. One or more positive cutaneous tests of a moderate or marked degree were exhibited by 100 of the patients. They were not regarded as clinically significant, since in many the sensitization did not adequately explain the allergy, and the elimination did not effect any improvement in the asthma of many patients. The maxillary membranes were obtained by the Caldwell-Luc operation performed during a quiescent state. Bacteriologic examination was made of 365 washings from the maxillary and sphenoidal sinuses, 130 polyps and membranes removed from the ethmoidal and sphenoidal sinuses and 108 membranes removed from the maxillary sinuses. *Staphylococcus* was found in 60 per cent of the sinus washings. It was also the most frequent organism in the sinus membranes. Hemolytic streptococci were found more frequently in the antral membranes (25 per cent) than in the sinus washings (11.7 per cent) or in the ethmoidal and sphenoidal membranes (8.5 per cent). *Pneumococcus* and *Streptococcus viridans* were present much more frequently in the washings and in ethmoidal and sphenoidal membranes than in the antral membranes. The frequent finding of the hemolytic streptococcus in the antral membranes indicates its importance as an agent of infection. A clear return-flow from antral irrigation may be sterile, but a heavy growth of one

or more organisms may be cultured from membranes removed at operation. Sixty-four cases with a positive culture of the washings showed only two membranes with no growth, although special stains showed the presence of bacteria in the tissue. Of the 108 cultures of the antral membranes forty-seven showed a growth of an organism which had not been recovered in the cultures of the previous washings. This does not mean that certain organisms found in the washings were not present also in some of the antral membranes. The cultures of the membranes of the two antrums occasionally showed different organisms and often different from those in the ethmoidal membranes. Twenty per cent of the ethmoidal and sphenoidal membrane cultures and 12 per cent of the sinus washing cultures were negative. Cultures of the ethmoidal and sphenoidal membranes showed *staphylococci* more frequently than the cultures of the washings by 14 per cent. *Staphylococci* were present in pure culture in 150 of the 365 washings, in fifty-nine of the 130 ethmoidal and sphenoidal membranes and in nineteen of the 108 antral membranes. Hemolytic streptococci were present in pure culture in twenty-three of the 365 washings and in twenty-four of the 238 sinus membranes. More than one organism was cultured from ninety-eight of the 365 washings and from seventy-one of the 108 antral membranes. The fact that only 4 per cent of the antral membranes showed no growth indicates the importance of the sinus membrane as a focus of infection. The negative cultures are explained by the fact that earlier in their work mucous polyps were opened and cultured from within, whereas now they make a culture of the polyp sac and the underlying membranes which are the source of the infection. Of the antral membranes 95 per cent and of the ethmoidal and sphenoidal membranes 80 per cent showed bacteriologic evidence of infection. Streptococci of all types cultured from the 238 sinus membranes were found in 44 per cent. This is far below the 94.5 per cent that Kistner reported for his group of 400 sinus membrane cultures. It is possible that the membranes found in nonpurulent sinusitis, as Kistner describes it, may be more frequently infected with streptococci than the hyperplastic membranes found in their allergic cases. The figures for the occurrence of streptococci in the sinus washings compare favorably with those of many other investigators.

Heart Murmurs in Newborn Infants.—Lyon and his associates encountered 147 newborn infants, among a total of 7,673, with heart murmurs. They were able to follow the course of ninety-two in later life. Heart murmurs were somewhat more frequent in the Negro infants than in the white infants. The seventy-six white infants constituted 1.6 per cent of a total number of white full term babies, while the seventy-one Negro infants with murmurs constituted 2.4 per cent of the total number of Negro infants. There were seventy boys (1.8 per cent) and seventy-seven girls (2 per cent). These infants were classified according to the month of their birth, and although there was a slight increase in the incidence in the fall and winter months the differences were not great. Further analysis would be necessary to demonstrate that the different seasons with their variations in diet and vitamin intake had any influence on the incidence of murmurs. The factor of birth weight and its influence on murmurs was not borne out, although they were somewhat more frequent in infants weighing from 9 to 10 pounds (about 4,000 to 4,500 Gm.) than in other weight groups. The incidence of murmurs in the infants of the entire group of white mothers was 1.9 per cent, and of mothers with positive serologic reactions only 1.3 per cent. The respective figures for infants of Negro mothers were 3.1 and 2.6 per cent. Syphilis apparently had no part in the causation of cardiac murmurs in newborn infants. Almost all the murmurs heard in this series were systolic. In only two instances was there a diastolic murmur associated with a systolic murmur. The murmurs were blowing in quality in about half of the group, and in the other half they were rough or musical. The majority were audible over the entire precordium and were usually loudest at the apex or in the region of the third costal interspace a little to the left of the sternum. In forty-one of eighty-four infants observed for a week a murmur was heard during the first twenty-four hours of life but had disappeared by the third to sixth day; in twenty the murmurs were heard on both the first and sixth days of life and in the remaining twenty-three the murmur was not heard on the first day but only on the fifth or sixth day. Of the ninety-two infants followed after dismissal, four died between four days and nine months after birth. Of the remaining eighty-eight, thirty-one were seen only once, thirty-six from two to ten times and twenty-one on more than ten occasions. Practically all these infants were examined about six months after dismissal and forty-five were followed until they were more than 1 year of age. The murmurs had persisted in fourteen instances; in three a patency of the interventricular septum was suspected but in the others no definite diagnosis could be made. Mild cyanosis was observed in two infants. The hearts of the remaining seventy-four infants seemed normal except for inconstant systolic murmur in two instances and extrasystoles in one other. No distinctive signs occurred during the first week of life to indicate which murmurs would persist for longer periods. The quality of the murmurs and their location during the first week were practically the same in the infants with permanent murmurs as in those with temporary murmurs.

Prophylaxis and Treatment of Poliomyelitis with Azosulfamide.—During an epidemic of poliomyelitis Rhett gave azosulfamide as a prophylactic to 440 acutely ill children. The daily dose was 0.065 Gm. per pound of body weight. In one of these children a transient paralysis developed on the fifth day of illness. The mother of this child did not keep up the maintenance dose of the drug. Symptoms subsided when full dosage was resumed, and paralysis was recovered from during the three weeks of quarantine. Meningeal symptoms developed on the fifth day of illness in two other children under similar circumstances; that is, noncontinuance of the maintenance dose. These symptoms subsided without paralysis when the full dosage of the drug was once more administered. In fourteen cases of poliomyelitis the drug was given in the preparalytic stage. Paralysis developed in only one of these. Eight children with a clinical diagnosis of meningeal involvement of poliomyelitis recovered under azosulfamide medication without paralysis. These cases are not reported as positive as they were not confirmed by spinal fluid examination. Eleven patients with paralytic involvement were treated with azosulfamide. Toxic symptoms subsided in from twenty-four to forty-eight hours, and there was no progression in paralytic involvement after an adequate dosage of the drug was reached and maintained for from twenty-four to forty-eight hours. There were no deaths in the acute phase of the disease. There were two patients presenting acute fulminating onset of the disease with involvement of all extremities and respiratory musculature. The respirator was necessary. One of these patients died two months later while convalescing and recovering some respiratory function. Death was caused apparently by an attack of asthma, from which she had suffered for several years.

Antistreptococcus Serum in Acute Poliomyelitis.—Rosenow compares the results obtained in the treatment of 221 patients with acute poliomyelitis receiving antistreptococcus serum since 1928 under his supervision or under the supervision of physicians to whom he sent the serum and the effects of the disease among 116 similar patients living under comparable conditions who did not receive the serum. The initial symptoms in the group in which serum was administered were somewhat more severe than the initial symptoms in the control group. The results are contrasted on the basis of mortality and residual paralysis. Of the patients who received the serum ten died, whereas twenty-three of the control patients died. Of the 211 patients who received serum and who survived 161 recovered without having residual paralysis, twenty-nine had slight paralysis, fourteen had moderate residual paralysis and only seven

(3.3 per cent) had severe residual paralysis. Of the ninety-three control patients who survived, only thirty-four did not have residual paralysis, ten had slight paralysis, seventeen had moderate paralysis and thirty-two (34.4 per cent) severe paralysis. The number of injections and the total amount of serum administered were recorded for 188 patients; a total of 508 injections was administered, representing 7,670 cc., or an average of about 15 cc. at each injection, and 40 cc. for each patient. The amount of serum administered per patient ranged from 10 to 200 cc. Only one person had an immediate severe reaction to the serum, three a moderate reaction, three a slight reaction and 146 no immediate reaction. Six patients had severe late reactions, fifteen moderate reactions, twelve slight reactions and 120 no late reaction. Of the ten patients who died in the serum group, all had marked paralysis before the serum was administered. Of the seven patients to whom serum was administered and who recovered with severe residual paralysis, five had severe paralysis before treatment with serum was instituted and two had moderate paralysis. In only one instance was the first injection made as early as the second day after the onset of symptoms. Of the twenty-nine patients who had slight residual paralysis after treatment, twenty-one had a severe degree of paralysis and two did not have any paralysis at the time of the first injection of serum. Of the 161 patients who eventually recovered without residual paralysis 106 did not have paralysis, eight had slight paralysis, six had moderate paralysis and forty-one had severe paralysis at the time of the first injection of serum. The degree of residual paralysis was in direct proportion to the duration of the disease before the administration of the serum. Thus, among those patients who recovered with severe residual paralysis the average duration of the disease was 4.3 days, among those with moderate residual paralysis it was 4.7 days, among those with slight residual paralysis it was 3.5 days and among those with no residual paralysis it was 2.3 days. The much lower mortality (4.5 per cent) and incidence of severe residual paralysis (3.3 per cent) of the patients given serum in comparison with the mortality (19.8 per cent) and incidence (34.4 per cent) of severe residual paralysis of the controls seem directly attributable to the action of the anti-streptococcus serum. Restless, nervous children often fell asleep soon after receiving the first injection of serum. Headache and pain in the involved extremity or part often were lessened or relieved. The temperature, especially among patients in the preparalytic stages, rapidly fell to normal, usually after an initial transient elevation. Progressive paralysis often was seemingly arrested. Restoration of muscle function was more rapid among patients who received serum. These favorable results, obtained since 1928, are in strict accord with those previously reported.

Treatment of Rheumatoid Arthritis with Sulfur.—

According to Abrams and Bauer the evidence that the sulfur content of articular cartilage is reduced in patients with rheumatoid arthritis is meager and not well established. They point out the difficulties encountered in evaluating the results of therapy in rheumatoid arthritis and stress the precautions and the necessity of a rigid control in accurate estimation. In their series of patients (twelve ambulatory and two hospitalized) all

but two had been observed for periods varying from one to five years before sulfur therapy was instituted. The two exceptions had been on an established basic regimen for months prior to hospitalization without obtaining any appreciable effect. The same basic regimen of a high vitamin, high caloric diet, added vitamins in the form of cod liver oil and yeast, daily physical therapy and constant rations of acetylsalicylic acid, allowed during the pretreatment period, was continued during the sulfur therapy and post-treatment periods. Two of these patients received two series of injections. Colloidal sulfur was given intravenously to twelve patients (fourteen courses) and intramuscularly to two. Ten patients received a total of from 310 to 370 mg. of colloidal sulfur over a period of from six to eight weeks. In order to establish that larger doses (1,000 mg. or more) were no more efficacious than the previously mentioned smaller ones, three patients were given 1,080, 1,200 and 2,980 mg. respectively. Twenty mg. was administered as an initial dose, except for two of the patients. Subsequent injections of 30 mg. each were given to all patients except those receiving the larger doses. In the latter 50 mg. was given as a second dose and 100 mg. subsequently. The results indicate that colloidal sulfur, even when administered in large doses, does not alter the course of rheumatoid arthritis. While the number of cases so treated is small, the uniformity of the results renders them significant. Colloidal sulfur therapy in the authors' opinion is but another antirheumatic remedy which can be dispensed with with considerable saving of expense to the patient. The data presented here are in agreement with the action taken by the Council on Pharmacy and Chemistry of the American Medical Association, which has been unwilling to include in its list of new and nonofficial remedies any of the colloidal sulfur preparations now on the market.

Endocrine Treatment of Senile Vulvovaginitis.—Finkler and Marks administered estrogen to fifty patients presenting symptoms of senile vulvovaginitis. The symptoms consisted of pruritus vulvae, pruritus ani, and dyspareunia due to partial stenosis of the introitus and sclerosing changes in the vulva and perineum. Most of these patients presented in addition to the local symptoms varying degrees of vasomotor and mental disturbances. The estrogen preparations were administered by injection, inunction of the vulvovaginal area, suppository and/or orally. For the purpose of comparison, some of the patients were shifted from one type of therapy to another when, after a period of rest, regression had occurred. The effect of the therapy was studied and checked by bio-assays, vaginal smear and endometrial and vaginal biopsy. The selection of the type of therapy to be used varies from patient to patient and depends on the severity of the symptoms, the local condition present, whether local or general symptoms predominate and the cooperation of the patient. Varying degrees of improvement in local and general symptoms resulted from all four routes of administration of the estrogen. The greatest relief from general symptoms was obtained from intramuscular injections. Oral medication used in adequate potency gave similar relief. Amelioration of symptoms was achieved in most of the fifty patients. Incomplete response or failure was observed in twelve patients who had complicating medical conditions such as diabetes, eczema, extensive leukoplakia, atrophy due to radiation therapy and vulvectomy for a preexisting kraurosis vulvae, hypertrophic pathologic changes in the vulva, psoriasis and psychoneurosis.

Sulfapyridine and Specific Serum in Pneumonia.—Rueggeger and his associates compared the efficacy of sulfapyridine with type specific antipneumococcus serum. The alternate case method was employed for a period of approximately six months. Only those patients who had had pneumonia for less than 120 hours were included in the study. Types I to VIII were alternated within the individual types; the higher types IX to XXXII were alternated without regard to type. The dosage of serum was from 100,000 to 200,000 units for the patients without bacteremia and roughly double these amounts for those with bacteremia. Patients receiving sulfapyridine were given 2 Gm. of the drug immediately and 1 Gm. every four hours night and day. The drug was administered by mouth. If vomiting occurred within thirty minutes the dose was repeated. There were twenty-nine men and sixteen women in the serum treated group and twenty-nine men and twenty women in the group receiving sulfapyridine. The serum treated group contained more patients in whom the pulmonary lesion on admission was limited to one lobe. In each group seven patients had bacteremia; of these, one of the serum treated group and two of those receiving the drug died. A symptom or symptoms which presumably represented clinical serum sickness developed in twelve patients. One patient showed no response to serum and had a spontaneous crisis four days later. Empyema developed in two patients subsequent to clinical improvement after serum therapy; both required surgical drainage. The average dose of sulfapyridine for the entire series was about 33 Gm. Ingestion of the drug was followed in slightly more than half of the patients by nausea and/or vomiting. In no instance was therapy interrupted because of vomiting. Two patients showed sharp decrease in the number of circulating leukocytes, with a return to normal after discontinuance of the drug. It was observed in three other patients that a relative leukopenia was not a contraindication to this form of chemotherapy. One patient showed a rapid decrease in his erythrocyte count during drug therapy; iron therapy and discontinuance of the drug was followed promptly by a restoration to normal. The most dramatic effect of sulfapyridine therapy was the critical drop in temperature, which occurred usually within the first eighteen hours of therapy. Unlike spontaneous or serum induced crises, this drop of temperature was rarely associated with marked clinical improvement. There was no apparent relation between the blood sulfapyridine level and decrease in temperature; in several instances it actually occurred when only a trace of the drug could be demonstrated in the blood. It apparently cleared the blood stream of seven of the eight patients who had bacteremia. Empyema developed in only one patient in this group and his pleural cavity was sterilized without resort to surgical intervention. Sterilization took place

by a gradual reduction in the number of encapsulated organisms rather than by a decapsulation of the organism. The authors feel that neither specific serum nor sulfapyridine is entitled to an exclusive position in the therapy of pneumococcal disease of the lungs. There is no apparent incompatibility between the two agents and it is suggested that the best results can be obtained by combining the two. There were two fatalities among the forty-five patients treated with specific antipneumococcus serum and six among the forty-nine patients treated with sulfapyridine.

Statistical Study of Pneumonia.—Faller and his co-workers obtained through questionnaires fairly complete data on 5,977 cases of pneumonia occurring in Pennsylvania from January 1938 to July 1939. The gross mortality was 22.1 per cent, or 1,321 deaths. The highest incidence was during the winter and early spring months. A relatively high incidence was demonstrated in infancy and early childhood, with a relatively low incidence in middle life and a greater prevalence of both lobar pneumonia and bronchopneumonia in later life. The incidence did not differ markedly for the two sexes, but there was a greater incidence of both lobar pneumonia and bronchopneumonia in male than in female patients. The incidence of the ten most common types in order of frequency was I, II, III, VII, VIII, V, IV, XIV, VI and XIX. There was a tendency of the higher types of pneumonia to be more frequent in childhood. The mortality for pneumonia patients treated by non-specific methods was 30.83 per cent and 10.69 per cent for those treated with sulfapyridine. The mortality for patients treated with specific antipneumococcus serum was 17.84 per cent. The mortality for patients treated with both serum and sulfapyridine was higher (14.67 per cent) than for those treated with sulfapyridine alone. The probable explanation for this is that sulfapyridine therapy is used too long before serum is begun. If a beneficial response is to be obtained with sulfapyridine, it should be evident within twenty-four hours. The mortality increased with each day for which specific serum treatment was delayed. The lowest mortality rates were with sulfapyridine, and with sulfapyridine with serum. In the cases in which serum and sulfapyridine were used on the first day of the disease no deaths occurred. Serum used after the third day, either with or without sulfapyridine, did not lower the mortality. A lamentably small number of blood cultures were performed among the pneumonia patients throughout the state as a whole. Because of the prognostic significance of a positive blood culture and its guidance as to the dosage of serum, blood cultures should be performed in a routine manner. Otitis media and empyema accounted for the majority of complications in children. Empyema was the most common complication in adults, with a mor-

tality of 22.4 per cent. Only one case of granulocytopenia was reported. It was fatal and occurred in a sulfapyridine-treated case. From a survey of the recent literature on pneumonia the authors collected 5,554 additional serum-treated cases and 3,608 additional sulfapyridine-treated cases. The mortality for the serum-treated cases was 15.79 and for the sulfapyridine-treated cases 6.26 per cent. Mortality for the combined 6,462 serum-treated cases was 16.07 per cent and for the 4,739 sulfapyridine-treated cases 7.32 per cent.

Anemia of the Newborn.—Dwyer and Neff cite the cases of two newborn infants with anemia associated with erythroblastosis and icterus, in which blood transfusion was followed promptly by a return to normal. Another newborn infant with anemia, in whom erythroblastosis and icterus were not present, did not respond to repeated transfusions. However, the use of liver extract hypodermically was followed by the appearance of

reticulocytes and immature granulocytes immediately, with a gradual return to normal blood values. This suggests that erythroblastic hemolytic anemia of the newborn is differentiated from the nonerythroblastic type not only clinically, hematologically and pathologically but possibly also by the response to blood transfusions. The case of a fourth infant with a severe grade of anemia of nearly four years duration, which was refractive to transfusions as well as liver and iron therapy, is reported. The anemia began in the newborn period and, unlike the majority of cases of aplastic anemia, the aplasia was confined to the erythropoietic organs. Postmortem observations were not characteristic of aplastic anemia. In a rather loose grouping of these rare forms of anemia in early life it is regarded as a case of hypoplastic-aplastic anemia of the newborn.

Malarial Therapy in Dementia Paralytica.—In the past seven years 304 cases have been treated with tertian malaria at the Milledgeville State Hospital as a routine treatment for neurosyphilis, according to Mays and his associates. Nine months ago a strain of quartan malaria was introduced for cases which were immune to the tertian strain and for cases in which the serums were still strongly positive after treatment with tertian malaria. Twenty-two of the 304 patients receiving the tertian strain were later treated with the quartan strain of malaria; fifteen other patients were also treated with quartan malaria. Their experience with the two types of malaria suggested that the quartan malaria is preferable to the tertian malaria because of its higher improvement rate, its lower death rate and its more prolonged temperature elevation. The most favorable reaction was obtained in the grandiose-excited type of patient and the least favorable outlook for recovery was in the simple deteriorated type. It appears that the severity of the paroxysms, rather than their number, is the therapeutic desideratum. In debilitated patients it is frequently advisable to precede malarial therapy with a course of tryparsamide and thiobismol. The death rate can be materially lowered by careful observation and proper symptomatic treatment of the patient during the acute and postmalarial period. During the febrile periods the patient should receive fruit juices and sodium chloride. Anemia and cachexia will improve with tube feeding, ferrous sulfate administration and repeated small transfusions of whole blood. Psychotic symptoms, such as hallucinations, grandiose or paranoid delusions and hypochondria, frequently show an exacerbation during the period of acute malaria, but these clear up readily with the administration of quinine. Convulsions appearing in cases of dementia paralytica tend to decrease the recovery rate and to increase the mortality rate. There was no significant improvement in the neurologic symptoms following malarial therapy.

Stomatitis in Childhood.—Among 115 children suffering from stomatitis Parsons found that it was not always possible to classify the cases into general types: aphthous, catarrhal, mycotic or thrush, ulcerative, gangrenous or noma and symptomatic stomatitis. Generally the clinical and bacteriologic features of the stomatitis of children less than 2 years of age differed from that of older children. Sixty-seven of the 115 children were girls. The youngest patient was 13 days old and the oldest 11 years. More than half of the cases occurred in children less than 2 years of age and four fifths before the third birthday. The incidence of the disease diminished progressively as age increased. The most common symptoms were sore mouth, anorexia and malaise. Diarrhea was common in children of the young group, constipation in the older children. Vomiting was frequent in all. Pyrexia was considerably higher in the older group. Toxic, grayish pallor without obvious anemia was an exceedingly common symptom. Stomatitis occurred in the young artificially fed children or those who sucked dummies. It was usually due to thrush, even when aphthous ulceration was the chief sign. There was little or no odor, and the cervical glands were not involved. Gastro-enteritis was an extremely serious complication. There was no distinct division between this type of stomatitis and the one occurring in older children. The stomatitis of older children was of the Vincent type but was often complicated by aphthous ulceration, while inflammation, offensive odor and glandular enlargement were the rule. The organisms concerned were anaerobes, but an underlying organism of unknown character, possibly a virus, was probably the cause, and aphthous ulceration merely a symptom. An absolute and relative monocytosis was found in many cases of stomatitis in all age groups. It was quite characteristic but the reason for its occurrence is unknown. Various forms of treatment were tried but local application of either 1 per cent aqueous solution of gentian violet or tincture of merthiolate was most effective. Symptomatic relief was particularly rapid. There was no evidence to implicate vitamin deficiency.

Pyramidal Lesion in Monkey. Sarah S. Tower.—p. 36.
Angio-Architecture of Gliomas. J. Hardman.—p. 91.

Gliomas and Their Significance.—Scherer studied in necropsies the mode of growth of 120 cases of glioma. Celloidin sections including the whole tumor with surrounding tissues from one end of the glioma to the other were utilized in the study. This method is indispensable, as the majority of gliomas are more extensive than their macroscopic aspect might lead one to suppose. All gliomas, except ependymoma, show an infiltrative type of growth, although in widely differing degrees, by no means corresponding to the more or less "malignant" aspect of the glioma cells. Cerebral astrocytomas are the most invasive of all cerebral tumors, while glioblastomas include a considerable percentage of fairly well defined neoplasms with a narrow zone of growth. The cytologic tumor entities include gliomas of quite different types of growth, proving that cytology and histogenesis are insufficient to characterize the biologic behavior of a given glioma. Only about 30 per cent are relatively circumscribed tumors; their real extent exceeds but moderately their macroscopically visible limits. This group includes oligodendrogliomas, many cerebellar astrocytomas and certain medulloblastomas. Factors underlying this surgically rather favorable mode of growth are (1) a narrow, compact

zone of growth, (2) a halting of the tumor at certain preexisting structures, especially the cortex, and (3) degenerative processes at the edge. Tumors of the hippocampal region and the septum lucidum grow frequently in the form of round, expansive masses in the ventricular cavity. About 60 per cent of gliomas have a more diffuse character with a widespread zone of growth considerably exceeding the macroscopically visible "tumor" and involving more than one lobe. Nearly 35 per cent show what is probably a secondary diffuse growth, while 25 per cent must be considered as primarily diffuse neoplastic processes forming no circumscribed tumor. All cerebral astrocytomas belong to this group. In the common case of malignant dedifferentiation of an astrocytoma into a glioblastoma, often the glioblastoma alone is visible as a macroscopic "tumor," surrounded by a large astrocytoma zone the true character of which is discovered only by microscopic examination. About 10 per cent of gliomas show a primarily multicentric type of growth and in half of these cases this multicentricity is visible only on complete microscopic study. The macroscopic examination shows only one main tumor. Infiltration and destruction by growth are by no means necessarily associated in gliomas. Long-continued preservation of nerve cells and fibers in the midst of tumor tissue is not specific for astrocytomas (although most constant) but occurs also in glioblastomas.

Sulfonamides in Lupus Erythematosus.—Barber's experience in the last twenty years strengthened his earlier (1915) belief that in some cases of lupus erythematosus the cutaneous reaction may be due to streptococci and possibly other infections. He employed sulfonamides in lupus erythematosus for two and a half years. Most of the patients were investigated to determine whether tuberculous, streptococci or other chronic infections were present. In the few in whom tuberculosis

appeared likely to be responsible the eruption was not benefited. In most cases a chronic and often widespread streptococcic infection was found. When such foci were present they were removed before treatment with sulfonamides was begun. In some no foci were discovered but the patients gave a history of previous removal of foci or of acute diseases presumably streptococcic in origin, such as recurrent tonsillitis, scarlet fever or rheumatic fever. Most patients felt acutely ill after azo-sulfamide or sulfapyridine therapy for from eight to fourteen days. Their temperature rose, sometimes preceded by a chill. In some cases a generalized scarlatiniform eruption appeared. This was regarded as due to the liberation of streptococcic toxin by the drug from latent foci of infection. It differs from other types of eruption provoked by these drugs. This scarlatiniform erythema did not recur after subsequent administration of the drug. In several cases focal reactions were evident in the patches of lupus erythematosus. The reactions at times were accompanied by severe rheumatic pains and at times by swelling and tenderness of the lymph nodes. The drug was discontinued when the reactions developed, and the symptoms rapidly subsided. The therapeutic effects were good. Some patients had previously received gold salts or bismuth compounds but they declared that the effects of azosulfamide or of sulfapyridine were superior. Several patients had relapses after their lesions had entirely or partially disappeared. In no other disease has the author observed reactions comparable to those which have developed with such remarkable uniformity in lupus erythematosus. The severity of the reactions makes it imperative that the patient be warned that such reactions are likely to develop and that the drug be omitted as soon as symptoms arise. Ambulatory treatment should never be attempted in the presence of an acute, widespread eruption. The patient must rest in bed for several days before beginning a course of the drug. The dose was seldom more than one tablet three times a day and was often less.

Diluents for Stored Blood.—Maizels and Whittaker investigated the effect of tonicity and the p_H on the survival of cells in stored blood. They found that the cells of blood stored with the standard citrate-saline solution (0.85 per cent of sodium chloride, 1.05 per cent of sodium citrate), which is hypertonic, are hypertonic, whereas cells stored with a truly isotonic solution (0.43 per cent of sodium chloride, 1.05 per cent of sodium citrate) are isotonic. After a month's storage the hypertonic cells show more hemolysis. If the unhemolyzed cells of each system are then mixed with fresh normal plasma, the hypertonic erythrocytes show a further 50 per cent hemolysis and the isotonic cells show no lysis at all. Blood cells stored with a truly isotonic anticoagulant solution are therefore much more likely to survive after transfusion. If storage is prolonged, sodium salts flow into the cells, which swell and finally hemolyze. If acid is added to a saline-citrate-blood mixture so as to decrease the p_H to about 6.6, hemolysis is reduced by about half, probably owing to decreased penetration of cation at low p_H . If carbohydrate is added to stored blood, sodium penetration and cell swelling are decreased, and at six weeks hemolysis is about a tenth of that observed in simple salt solutions. A suitable anticoagulant diluent for blood is 0.43 per cent of sodium chloride and 1.05 per cent of sodium citrate. It is desirable to add dextrose or dextrin in a final concentration of 1 and 3 per cent, respectively, to improve preservation. If this is done the system becomes slightly more acid. To counteract cell swelling due to acidity it may be desirable to increase the sodium chloride in the solution to 0.5 per cent.

Cause of Breech Presentation.—According to Vartan, most of the factors reported as causes of breech presentation at term rarely occur. He concludes that either the "cause" is so rare as to be almost a chance coincidence or that the cause in almost every case is unknown. An analysis of 969 cases of breech delivery demonstrated that it is wrong to assert that the cause of the breech presentation at term is a pelvic anomaly which prevents the head from entering. Such conditions cause the oblique position. The cause of breech presentation persisting till term is to be seen in the failure of the fetus to undergo spontaneous cephalic version. The fetus is prevented from undergoing version by its extended attitude in 37.3 per cent of the cases, by the presence of another fetus in the uterus in

23.6 per cent of the cases, and by prematurity in 9 per cent. In 22.9 per cent of the cases no cause is recorded. The percentage of cases in which placenta praevia is associated is so small as to make it doubtful whether this can be called an etiologic factor. For the same reason contracted pelvis cannot be regarded as an etiologic factor. Pelvic tumors, abnormally shaped uterus, hydrocephalus, hydramnios and anencephaly are too rare to be of significance.

*Preliminary Observations on Use of Convalescent Serum in Treatment of Acute Rheumatism. C. A. Green, A. J. Glazebrook, S. Thomson and W. A. Hopkins.—p. 275.

Convalescent Serum in Acute Rheumatism.—Green and his associates observed a considerable amount of acute rheumatism in communities of young male adults engaged in strenuous physical training. In the majority of cases nasopharyngeal infection antedated the insidious onset of stiffness and pain in one or more joints. In others the disease appeared with hyperpyrexia, sweating and polyarthritides. Large effusions were not common, but tenderness, slight puffiness and edema of surrounding tissues were common. The joint lesions rapidly improved and left no permanent injury. The initial pyrexia rarely lasted longer than one week but in exceptional cases persisted for months. Remissions and relapses occurred frequently. Cardiac complications were frequent, despite the apparent mildness of infection. A number of patients did not show any tendency to develop cardiac lesions. As the patients were otherwise healthy young adults, it was decided that serum obtained from them during convalescence should be tried in the acute phases of the disease in subsequent cases. From 300 to 400 cc. of blood was obtained between the fourth and eighth week after the temperature had settled. Criteria of suitability included good general condition, absence of cardiac complications and an almost normal erythrocyte sedimentation rate. Following withdrawal of the blood, the serum was separated, filtered and preserved by the addition of phenol. The serum was subjected to the Wassermann and the routine sterility tests. This type of serum has been used in the treatment of fifteen patients. The serum was given either intramuscularly or intravenously in daily doses of from 10 to 20 cc. The injections were usually repeated for several days. Ten patients were treated with serum alone and seven of these, six with primary attacks and one with a recurrence, reacted favorably. In the five cases of the second group, serum therapy supplemented other treatment such as exhibition of salicylates. Three of these five patients returned to work without carditis. The authors gained the impression that, when given in the early stages of an attack, serum apparently reduced the period of pyrexia, particularly in primary attacks. Arthritic pain was relieved in such cases. The volume of serum was not large enough to permit really adequate dosage in every case, but the results obtained justify further extension of this method.

*Case of Antepartum Peritonitis of Undetermined Origin: General Review of Peritonitis of Pregnancy. A. Laffont and M. Piétri.—p. 565.

Peritonitis of Pregnancy.—Laffont and Piétri report a case of acute generalized antepartum peritonitis of obscure origin in which surgical exploration failed to reveal the source. The particular susceptibility of the peritoneum of pregnant women is the decisive factor in peritonitis of obscure origin. Microbic inoculation, however indispensable, exerts its action only because of this factor. It is the energy of the peritoneum which increases the power of invasion of a perhaps minimal microbic inoculation. This explains the paucity of surgical and post-mortem observations. The incidence of this form of peritonitis is insignificant. Some of the cases arise from an indisputably septic focus, such as peritonitis supervening on a cutaneous pneumococcal or staphylococcal infection. There is a group of cases in which the following factors are of etiologic significance: vulnerability of the peritoneum of pregnancy, occult infection of the serosa without a rupture of a viscus, monomicrobism as opposed to the multimicrobic invasion of perforating peritonitis, almost invariable death of the fetus in premature delivery and its occurrence in the last trimester of pregnancy. Nine similar cases are analyzed. The colon bacillus is the common etiologic factor in this form of peritonitis, which is difficult to differentiate from the appendicular form. Except in the cases in which premature delivery is induced, the treatment consists in surgical intervention and drainage. The approach is made by way of the right iliac fossa in order to permit differentiation from appendicitis. The patient is given sufficient morphine to avoid premature delivery. The iliac incision calls for careful observation while one is awaiting the term. If the wound is not healed at term, it may be utilized in the performance of an atypical cesarean section.

*Average Diameter of Erythrocytes as Diagnostic Aid in Differentiation of Icteri. L. Schalm.—p. 312.

Roentgenologic Detection of Intraperitoneal Fluids.—Cosaccesco and his associates stress the diagnostic value of roentgen rays in determining the site and quantity of free fluids in acute abdominal lesions. Nine cases are analyzed from this point of view. The roentgen rays were particularly helpful in demonstrating lateral pus collections which might otherwise have been overlooked. A patient's failure to improve after ample drainage could be traced not to the development of fresh foci but to previously unrecognized pus accumulation. Although roentgenograms suffer from the disadvantage of being able to detect only significant peritoneal effusions, the demonstration of abundant extravasation of blood in shock or of multiple wound lesions is of value in making prompt surgical intervention mandatory. Abdominal roentgenoscopy may also be of value in the postoperative period with obscure manifestations.

Erythrocyte Diameter in Icterus.—Schalm investigated the diagnostic value of macrocytosis for distinguishing icterus in 100 cases other than cirrhosis of the liver. Only cases were considered in which bilirubinuria and a positive van den Bergh serum reaction were observed. The measurements were carried out by means of Pyper's halometer and were repeated during the course of the disease. The author found the diameter measurements decidedly valuable in distinguishing parenchymatous icterus from obstructive icterus. A normal average erythrocyte diameter or one not exceeding 0.7 micron, after icterus had existed for several weeks, indicated an uncomplicated occlusion of bile ducts, irrespective of the cause of obstruction. An average erythrocyte diameter attaining or exceeding 1 micron was proof of extensive destruction or of serious functional impairment of the parenchyma of the liver. The one exception to this observation was certain cases of carcinoma of the head

of the pancreas which disclosed a 1 micron diameter increase without concomitant parenchymatous lesions. Borderline measurements between 0.7 and 1 micron, noted in eleven of the 100 cases, were excluded from the inquiry. Repeated tests are necessary to determine whether an icterus presenting initially only a small increase in the average diameter of the erythrocytes might not show within a few days an unexpected enlargement. In all cases in which parenchymatous degeneration developed from simple biliary obstructions, the diameter of the erythrocytes increased by 1 micron or more.

Tuberculosis and Age.—Dressler and Gitermann investigated the relation between the form of tuberculosis and the age of patients examined at the Zurich polyclinic during 1933. They compare their observations with those of other investigators and arrive at practically the same conclusions. The curve of tuberculous morbidity discloses the maximum of incidence between the ages of 20 and 40; it is reached earlier in women (third decade) than in men (fourth decade). The number of cases is higher among men, with regard both to the open and to the closed tuberculosis. The various forms occur in the two sexes in approximately the same percentage. A curve indicating their distribution over the various age groups indicates that secondary infiltrations appear comparatively early, 50 per cent occurring before the age of 20 and 80 per cent before the age of 30. The early infiltrates are likewise most frequently found in young persons, particularly during the third decade of life. The chronic tertiary forms of tuberculosis develop later and are observed in the highest age groups. Open tuberculosis, in contradistinction to closed tuberculosis, is rarely restricted to one pulmonary field. The apexes and the upper field are especially often involved and about twice as frequent on the right as on the left side. Bilaterality is more frequent in open than in closed tuberculosis (56 and 29 per cent, respectively). Pleuritic complications (pleurisy and adhesions) occur with equal frequency in the two forms; that is, in approximately one third of the cases. Patients with early infiltrate are most often free from pleuritic complications, a factor that is important for collapse therapy. The pleuritic complication is usually (in from 80 to 90 per cent) ipsilateral with the pulmonary process. The preferred localization of the primary focus is the right lower field; then follow the left middle and lower fields.

Brucella Abortus Infection in Premature Infant.—Buser-Plüss reports the occurrence of undulant fever in an infant born two and one half months before term. She assumes that the infection was transmitted either in the uterus or by the breast milk. The typical picture of undulant fever gradually developed possibly because of the gradual decrease in immune bodies supplied by the mother or as the result of weakening by intercurrent diseases. The undulant fever persisted for months, terminating in a cure despite severe complications. The relatively benign character of the disease indicated by the low agglutination titer in mother and child may have been the result of an earlier Brucella infection among the cattle belonging to the family. The premature infant had a Brucella abortus infection which presented typical aspects of undulant fever with numerous complications, especially on the part of the respiratory organs. An intra-uterine infection cannot be here established beyond a doubt, but the following points speak in its favor: (1) latent Brucella abortus infection of the

mother during or shortly before pregnancy, (2) premature birth in the sixth month, presumably as the result of the maternal infection, and (3) insidious appearance and slow development of undulant fever in the infant during the first months of life; that is, at an age which otherwise is immune against *Brucella abortus* infection.

Clinical Experiences with Helborsid.—Helborsid, according to Grossmann and Benzon, is a solution of hellebrin, crystallized pure glucoside of *Helleborus niger*. Hellebrin differs from helleborein in being about twenty times more active. Like strophanthin it is a glucoside of the second order, but, in contradistinction to strophanthin, its aqueous solutions are highly stable, retaining their efficacy for years. The pharmacologic properties of hellebrin greatly resemble those of strophanthin. The authors administered helborsid to seventy-four patients with forms of decompensation the result of valvular lesions, myocarditis and coronary sclerosis with or without angina pectoris. They excluded from treatment all patients with mild forms of decompensation in whom bed rest and small oral doses of digitalis produced the desired results. Helborsid was administered intravenously. The initial dose was 0.5 cc. of the solution containing 0.25 mg. of hellebrin, increased later to 1 cc. and rarely to 1.3 cc. The injection was given daily, occasionally twice daily, until the desired effect was obtained. The later treatment was intermittent, like that of modern strophanthin therapy. The total number of injections varied, a few patients receiving as many as thirty. Helborsid is a highly effective cardiac stimulant. Its action is similar and in some respects superior to that of strophanthin. It is less toxic and its secondary effects are either absent or appear later and in a milder form. This makes it possible to treat many patients with severe heart disease, in whom neither digitalis nor strophanthin can be employed because of the rapid development of secondary toxic effects.

Pleuropulmonary Reactions After Roentgen Therapy in Cancer of Breast. R. Camerini.—p. 18.

Juvenile Diabetes and Intracranial Hypertension.

Landogna Cassone made a clinical and roentgenologic diagnosis of intracranial hypertension in six of a group of ten children with diabetes. The clinical symptoms, such as frontal headache, vomiting, frequent nausea, hyperemia and edema of the papillary disk, were noted one or two years before the development of diabetes. The roentgenograms showed thinning of the cranium, finger-like shadows on the cranial bones, dilatation of the venous sinuses and alterations of the sella turcica. The author believes that juvenile diabetes is caused by a lesion of the hypothalamus and of the hypophysis, the result of an acquired hydrocephalus and increased intracranial tension. The hydrocephalus is either primary (serous meningitis) or secondary to early synostosis of the cranial bones. A proper medical regimen, diet and decompression are indicated. Decompression can be accomplished by antisyphilitic treatment (even if a diagnosis of syphilis is doubtful), by lumbar puncture repeated at monthly intervals or by trephining.

Circulatory Impairment and Nicotine.—Weicker reports observations on acute and chronic nicotine poisoning in twenty-four men between the ages of 17 and 53 who smoked daily between fifteen and fifty cigarettes. In a man aged 36 who smoked on an average fifty cigarettes daily for the last ten years, symptoms of acute nicotine poisoning appeared in the

form of a severe abdominal intoxication. Death ensued within eight hours. Necropsy revealed a cardiac infarct of the anterior wall with extensive lipid sclerosis of coronary vessels and the aorta. Acute or chronic cardiac infarcts were observed in seven men. In one of them, aged 53, who had been in the habit of smoking forty-five cigarettes daily, necropsy disclosed severe coronary sclerosis and an acute infarct of the anterior wall. Disturbances in the cardiac conduction were present in three men whose electrocardiograms disclosed prolongation of PQ and widening of QRS. In one, atrioventricular block developed suddenly as he was smoking a cigaret on an empty stomach. A man aged 43 who smoked about thirty cigarettes daily had coronary insufficiency. In eight younger men (average age 28) with a daily consumption of from twenty to fifty cigarettes, anginal symptoms were present. These patients frequently presented a bradycardia and steep and high T deflections and widening of the QRS complex in the cardiograms. Thrombo-angiitis obliterans was observed in four men. In two of these, nicotine was the only demonstrable external cause capable of impairing the peripheral circulation, and in the other two exposure to cold and dampness may have played a part. Some investigators believe that cigaret smoking is not necessarily the only cause of thrombo-angiitis obliterans but that it may contribute to its development because of the constricting influence of nicotine. The final solution of this problem is still impossible. Statistical studies indicate that patients with thrombo-angiitis obliterans are nearly always heavy smokers. Measures for the restriction or prevention of smoking, particularly among young persons, are discussed.

Vitamin C in Acute Infectious Diseases.—Szirmai investigated the therapeutic value of vitamin C in toxic diphtheria, in typhoid and in pneumonia over a period of three years. In toxic diphtheria with edema of the mucous membranes the death rate was greatly reduced when, in addition to the large doses of serum, ascorbic acid was given. As a rule, 300 mg. of ascorbic acid was administered intravenously, simultaneously with the serum, but in a separate syringe, so as not to impair the antitoxin. When intravenous injection was technically not possible, the acid was given intramuscularly. The parenteral administration of 300 mg. of ascorbic acid was repeated daily for from three to four days. In addition the patients were given for from 50 to 100 mg. of ascorbic acid by mouth three times daily for about a week. In mild typhoid, the patients were given the juice of two or three lemons daily. Patients with typhoid of moderate severity were given, in addition, 100 mg. of ascorbic acid by mouth three times daily. Patients with typhoid in a severe form were given daily intravenous injections of 300 mg. for from four to five days. Under this management intestinal hemorrhages were almost completely prevented. In diphtheria and in typhoid, favorable results were obtained even when the doses were not sufficient to produce saturation. In pneumonia, however, the deficit of vitamin C had to be completely compensated before therapeutic results could be noted. Children with lobar pneumonia were given intravenous injections of 300 mg. of ascorbic acid once or twice daily. According to the literature from 2,000 to 3,000 mg. is necessary to produce saturation in pneumonia patients. The author emphasizes that the mode of action of ascorbic acid in acute infectious diseases has not been explained and that therefore the ascorbic acid itself rather than its neutralized solutions should be administered.

Serologic Reactions in Carcinoma. H. Dietel.—p. 99.

Dextrose Therapy in Puerperal Eclampsia.—Albers reports on the use of strong concentrations of dextrose in a large percentage of fifty-five cases of toxemia of pregnancy, observed in a total of 3,965 deliveries, with five deaths. Dextrose was employed in sixteen cases presenting acute prodromal antepartum symptoms of eclampsia, in eighteen cases of intrapartum eclampsia and in several cases of postpartum eclampsia.

The remainder were cases of toxemia without cerebral manifestations and were managed with rest and a carbohydrate and raw vegetable diet. Dextrose was given intravenously in quantities of 100 cc. in a 50 per cent solution, administered during three to five minutes. In one case six injections were made, three of 100 cc. within five hours. Dextrose therapy was successful in eleven of the sixteen cases with preeclamptic symptoms and made delivery by the normal route possible. The remaining five presented complications and required surgical intervention. A single injection of 100 cc. was frequently sufficient to abort the onset after a few minutes. Dextrose therapy in the eighteen cases of intrapartum eclampsia had only a limited effect. In only six was it capable of inducing the complete dilatation of the cervix and of permitting normal delivery. The other twelve had to be managed surgically. In six cases of eclampsia, occurring for the first time post partum, complete relief was effected by a single injection and in three others only one subsequent attack was observed. The author stresses the necessity of strict clinical control, as patients will not carry out instructions spontaneously. He believes that dextrose achieves the same results as a lumbar puncture with less difficulty, at the same time correcting carbohydrate deficiency. To avoid recurrence of increased lumbar pressure and the danger of eclampsia, he employed forceps as the method of choice in completing the delivery. In cases in which erythrocytes and granule casts appeared in large quantities in the urinary sediment or in which an eclamptic onset recurred after the first injection, instrumental delivery was resorted to. Thrombosis of the injected vein is not to be feared even after several injections.

Elimination of Histidine in Urine.—Neuweiler and Grimm direct attention to the Kapeller-Adler pregnancy test, based on the fact that the urine of pregnancy contains large quantities of histidine. Other investigators observed that histidine elimination takes place not only during pregnancy but also in hepatic and allergic disorders. The histidinuria of hepatic disease has been ascribed to an altered function of the hepatic histidinase, and it has been suggested that that of pregnancy might be traceable to an inhibition of the hepatic histidinase by gonadotropic substance. Histidine has been detected in the urine of healthy men and children. The authors studied the question of histidinuria in nonpregnant and in puerperal women and determined the changes that may be produced in the elimination of histidine by the administration of histidine monohydrochloride and of vitamin C. Tests were made on 455 urines. Among twenty-five women whose pregnancy had not advanced beyond the fourth month there were twenty-three exhibiting histidinuria, whereas the 247 women in the more advanced stages of pregnancy all had histidinuria. Thus 99.3 per cent of the pregnant women eliminated histidine. Histidinuria was observed in only 15 per cent of the nonpregnant women. During the first days of the puerperium, urinary elimination of histidine was constantly observed. Daily control examinations on eight puerperal women disclosed that histidine elimination ceased in all from the tenth day on. It was not possible to reduce histidine elimination by saturation with vitamin C. By the administration of histidine monohydrochloride it was occasionally possible to increase the histidinuria and to induce a positive histidine reaction in nonpregnant women. A correct bromination is of great importance for the demonstration of histidine. Urines which contain nitrite must be brominated until a lemon yellow color results; urines free from nitrites until potassium iodide-starch paper turns blue. The blueness which develops in the urine, in contradistinction to that developing with pure histidine solution, can be extracted by butyl alcohol; this intensifies the sensitivity of the reaction.

Sickle Cell Anemia. K. Makrycostas.—p. 330.

Recurrent Peptic Ulcers of Jejunum.—According to Finsterer, recurrent jejunal peptic ulcers are wrongly regarded as surgically incurable. He reports successful results in nineteen out of twenty-three recurrent cases secured by means of radical resection. The patients were men between 26 and 56 who had undergone from two to seven abdominal operations previously. They were predominantly younger men (four under 30, five under 40), five of whom had gastric disorders from childhood. Seven of the eight patients between 50 and 56 had been under treatment from twenty-eight to thirty-nine years. Recurrence of ulceration was due to Y shaped anastomosis (twelve), to entero-anastomosis (five) and to insufficient resection (six). Eighteen of the cases showed complete absence of complaints after resection. One patient had been operated on seven times within four years and had been well after resection for the last four years. Several other patients had been restored to health for from ten to twelve years. The four deaths were due respectively to necrosis of the gastric wall, to cardiac lesions, to peritonitis and to a double gastrointestinal fistula. The author believes that failure to employ radical resection when it is indicated accounts in large part for the recurrence of these ulcers. Persistent symptoms after prolonged medical management constitute an indication for resection even in the absence of a gastroduodenal fistula or hemorrhages. Finsterer advocates resection of two thirds of the stomach and more when dilatation is present. He rejects Y shaped anastomosis except when subtotal resection is carried out to the extent of leaving one fifth or one sixth of the normal stomach. He believes that radical resection is indicated in youthful subjects with a history of recurrences. On the basis of more than 3,000 cases of stomach resection Finsterer recommends local anesthesia and splanchnic anesthesia for protracted operations.

Blood Chlorides and Surgery.—Bekerman studied the blood chloride levels of 115 surgical patients. The chloride content of patients in the preoperative period as expressed in milligrams per hundred cubic centimeters of sodium chloride varied within considerable limits from 425 to 590 mg., the figure in women being somewhat higher than in men. A fall in the blood chlorides was a constant sign in gastrointestinal obstruction. It is not, however, pathognomonic of obstruction since it may be present in diseases characterized by profuse vomiting or diarrhea, in pneumonia and in peritonitis. A fall in chlorides was constantly observed both in mechanical and in dynamic obstruction of any segment of the intestine. The degree of the fall depended on the duration of obstruction. A uniform fall of from 10 to 30 mg. was noted on the first postoperative day. This did not appear to depend on the anesthesia or on the character or duration of the operative intervention. A postoperative fall of more than 30 mg. the author considers indicative of a threatening complication, intestinal atony or pneumonia. A parallelism was observed between the extent of lowering of the blood chlorides and the gravity of symptoms of intoxication. A fall in the chloride level of 150 mg. as compared with the preoperative level, or a level below 300, signifies a grave state threatening the life of the patient. The author suggests repeated infusions of hypertonic solution of sodium chloride and blood transfusion in the preoperative period as a prophylaxis against postoperative complications in patients with a lowered preoperative blood chloride level.

Blood Bilirubin in Disease.—Germanov and Krylova investigated the blood bilirubin content and the qualitative van den Bergh reaction in 343 persons. Of these, ninety-eight were well and ninety-six had malaria, fifteen renal disease, seventeen mechanical jaundice, forty-one jaundice of parenchymatous origin, eight decompensated cardiovascular disease, eight hypertrophic cirrhosis of the liver, eight croupous pneumonia and fifty-two various diseases such as gastritis and bronchitis. Bilirubin determinations were made by the van den Bergh micro-method with the Autenrit colorimeter. The bilirubin content in healthy persons was found in amounts of from 0.25 to 0.45 mg. per hundred cubic centimeters. The indirect van den Bergh phase reaction was present. In malarial patients the bilirubin blood content was found to be increased to within 0.4 to 0.88 mg. per hundred cubic centimeters, occasionally up to 1 mg. In cases complicated with splenomegaly and jaundice the bilirubin content may rise above 1 mg. An indirect van den Bergh reaction is obtained. With treatment the bilirubin content rapidly returns to normal. In obstructive jaundice the bilirubin content rose as high as 20 mg. Both the direct rapid and the delayed bi-phasic van den Bergh reactions are present. In the parenchymatous jaundice the blood gives both the direct and the bi-phasic van den Bergh reaction, while the maximal bilirubin content amounted to 26.5 mg. per hundred cubic centimeters. The jaundice threshold is represented by 1.5 mg. content. In the early stages of cardiac decompensation the blood bilirubin content is not above normal; in grave decompensation it may rise above 1 mg. The van den Bergh reaction is indirect or delayed bi-phasic. In grave renal disease and in cases of chronic uremia the bilirubin blood content is markedly lowered. The authors conclude that the blood bilirubin content determination is valuable as an aid in the diagnosis, treatment and prognosis of a number of disease states such as malaria, jaundice, avitaminosis, renal disease and cardiovascular disease. The van den Bergh micro-method utilizing the Autenrit colorimeter yields accurate results.

Neurologic Complications in Epidemic Parotitis.—The occurrence of orchitis in about one third of the adult male patients indicates that parotitis is a generalized process rather than a local inflammation of the parotid gland. According to Snapper the virus of mumps attacks the central nervous system even more frequently than it does the testes. He cites a case in which parotitis became complicated with meningitis, meningo-radculitis and herpes zoster. Symptoms are observed in many cases of mumps which must be ascribed to involvement of the central nervous system. Severe headache, agitation, hallucinations, delirium, rigidity of the neck, Kernig's sign and slow pulse are to be regarded as symptoms of mumps-encephalitis. The meningo-encephalitis of mumps has a favorable prognosis. It is nearly always accompanied by a lymphocytosis of the spinal fluid, which may lead to the mistaken diagnosis of tuberculous meningitis. The peripheral nervous system may be involved; thus facial paralysis and paralysis of the palate or of the eye muscles have been observed after mumps. Since the disease process spreads from the meninges to the anterior roots, the author prefers the term meningo-radculitis to neuritis. Tetraplegia, neuro-ophthalmologic complications and deafness have

been observed. The central nervous system may become involved in apparently uncomplicated cases of parotitis without clinical symptoms of encephalitis and meningitis. A positive Nonne and Pandy test and a comparatively high lymphocyte count are detected in over 50 per cent of uncomplicated cases of mumps. Recent investigations have revealed that the virus is present in the spinal fluid of patients with mumps even in the absence of increased protein content and cell count. Rabbits given intraspinal injections of the cerebrospinal fluid of patients with mumps develop meningo-encephalitis. Herpes zoster is a comparatively rare complication of mumps. When present it is accompanied, as a rule, by objective symptoms of meningitis.

New Method of Conserving Blood.—In the course of research on the treatment of allergic diseases with desensitizing substances Corelli observed that blood collected with sodium thiosulfate remained fluid for a long time. This fact, coupled with the knowledge that thiosulfate is not toxic, suggested its use as a preservative. The thiosulfate anticoagulant, as prepared by the author for use in man, is innocuous. It has a desensitizing and antitoxic property particularly valuable in the prophylaxis of transfusion. From 5 to 6 cc. per hundred cubic centimeters of blood is sufficient if the blood is injected immediately, otherwise 7.5 cc. is added to 100 cc. This percentage is low when compared with other anticoagulant solutions. The red cells remain preserved for two or three weeks and longer; after that a moderate anisocytosis and microcytosis gradually set in. The platelets and the white cells, especially the neutrophils, decrease during the first five to ten days. Lymphocytes and monocytes are preserved for from twenty to thirty days. One thousand transfusions given in medical, surgical, obstetric and pediatric cases proved the tolerability of blood conserved with the author's method. In 92 per cent of the cases there was no reaction at all and in 8 per cent there was only a transient rise in temperature. Most of the transfusions were performed with blood one week old. The technic of collecting and transfusing the blood is simple. The author suggests that collection centers be created in large hospitals and clinics. The availability of conserved blood has its advantages, one of them being that it can be given by continuous drip. The author advises (1) the collection of the blood from a donor in a fasting state and its injection, when possible, to the recipient in the same state, (2) the use of compatible blood and, (3) when indicated, the injection of ephedrine, epinephrine or synephrin with caffeine when transfusion is begun.

Jejunal Feeding in Gastrocutaneous Fistula.—Kjølhede considers feeding through a jejunal sound a valuable method in postoperative gastrocutaneous and duodenocutaneous fistulas. He states that while introduction of the sound is difficult there is no further discomfort or risk for the patient, and he would first attempt to treat with this method all cases of fistula of the alimentary tract proximal to the jejunum. In the case reported fifty-one days passed without any sign of spontaneous healing, but the fistula closed after nine days of jejunal feeding.

EARLY MILD INFESTATION WITH THE PARASITE *TRICHINELLA* *SPIRALIS*

REPORT OF TEN CASES

JEROME E. ANDES, Ph.D., M.D.

ROBERT A. GREENE, Ph.D.
AND

EDWARD L. BREAZEALE, B.S.A.
TUCSON, ARIZ.

It is only within the last few years that the prevalence and significance of human infestation by the nematode *Trichinella spiralis* has been brought to light. A few decades ago, trichinella infestations were regarded as rare occurrences, chiefly because in few individuals did sufficient symptoms develop to allow a diagnosis. Recent studies of autopsy material, however, have definitely proved that this disease is very common. Practically all of the accurate cadaveric studies indicate that at least 10 per cent of the population of the United States have some encysted trichinella parasites in their muscles before death. The recent studies of Evans¹ give the incidence as between 5 and 50 per cent in the various cities of the United States, with an average figure of 37 per cent.

It is obvious that there is a marked lack of agreement between the data obtained from necropsy studies and the number of clinical cases reported. The reason for the discrepancy is probably to be found in the high percentage of undiagnosed and symptom-free cases. It is only plausible that in most cases the symptoms are so mild or so lacking in characteristic manifestations that *Trichinella spiralis* infestation is not even considered.

After ingestion of the meat infested with the trichinella (usually pork) the encysted parasites are freed from their capsules by the process of digestion. After growing to maturity and mating, the female burrows into the intestinal wall and starts to produce young in large numbers. Approximately a week passes before the period of multiplication begins. The symptoms during this first period are those of an intestinal irritation: nausea, vomiting, low grade fever, diarrhea and abdominal discomfort. The degree of severity of the symptoms must depend largely on the number of worms present, and it seems only too plausible that one pair of worms would produce little or no discomfort.

The second stage of the disease (period of dissemination, or larval migration) begins from the eighth to the tenth day and may last several weeks. During this time large numbers of larvae enter the blood and pass to all

parts of the body. Apparently only those that reach the skeletal muscles survive, and their encystment and digesting away of the surrounding muscle tissue are the cause of the characteristic muscle pain and tenderness that develop. The liberation of the muscle protein probably produces the accompanying fever, edema of the face, prostration, cachexia and anemia appearing at this time. The third stage is that of muscle encystment and recovery.

As stated previously, it is probable that a very small number of parasites in the intestinal tract would produce few if any symptoms. Even in the muscle encystment process, a fairly large number of larvae would need to invade the muscles to cause a noticeable soreness; consequently it would seem that it might be difficult or even impossible to diagnose very mild cases of trichinella infestation. Furthermore, it also seems plausible that the administering of an anthelmintic before the period of multiplication begins might stop the entire process at this point.

During the previous school year we had a number of cases (all within about ten days) which we feel were produced by infestation with the trichinella parasite. All were very mild in character except one, and this case was only moderately severe.

REPORT OF CASES

CASE 1.—J. L. O., a white youth aged 19, came to the clinic on Jan. 18, 1939, with a complaint of abdominal pain and discomfort. The symptoms had been present for about forty-eight hours. The abdominal discomfort was described as a dull continuous ache. There had been no vomiting or diarrhea, jaundice, belching or abnormal stools. He had been eating regularly up to the day of admission, and his bowels had been entirely normal. He had never had a qualitative dyspepsia and had never had any serious gastrointestinal disturbances during his life. He also stated that he had noticed a low grade fever and had had several chills since the onset. All the rest of the history was entirely irrelevant except that he had eaten some fresh pork about twenty-four hours before the onset of the symptoms.

The patient was well developed and well nourished and appeared ill. There were no gross abnormalities. His face was flushed and there was a definite puffiness about the eyes. A small amount of tenderness over the frontal sinuses with some postnasal dripping was present. The chest was entirely normal, the blood pressure being 120 systolic, 78 diastolic. The abdomen showed a palpable descending colon but no tenderness or other abnormal signs. The genitalia, skin and extremities were entirely normal. There was no muscle tenderness. The temperature was 98.4 F. and the pulse rate 74. He was admitted to the hospital with a diagnosis of chronic sinusitis, ileocolitis and possibly trichinosis.

The urine was entirely normal. The white count revealed 7,000 white cells, and the differential count showed 14 per cent eosinophils, 64 per cent neutrophils, 20 per cent lymphocytes and 2 per cent monocytes. A cutaneous sensitivity test with the trichina antigen was strongly positive. He was given 3 Gm. of tetrachlorethylene followed two hours later by 30 Gm. of magnesium sulfate.

From the Department of Health, University of Arizona, and the Arizona State Laboratory.
1. Evans, C. H., Jr.: J. Infect. Dis. 63: 337 (Nov.-Dec.) 1938.

The next day the count showed 7,000 cells with 16 per cent eosinophils. By evening he was greatly improved, and his temperature and pulse were entirely normal. The highest temperature noted while in the ward was 99.4 F. There was no muscle tenderness at any time while he was in the hospital. He was discharged with a diagnosis of early trichinosis. Permission for a biopsy was refused.

On February 19 (thirty-four days later) he came in for a check-up. He had not been ill since discharge. The examination was negative. A count revealed 7,400 white cells, with no eosinophils nor basophils, 85 per cent neutrophils, 13 per cent lymphocytes and 2 per cent monocytes. A second check-up on May 25 was again entirely negative. The count was 6,600 white cells with 64 per cent neutrophils, 32 per cent lymphocytes, 4 per cent monocytes and no eosinophils or basophils.

CASE 2.—Miss B. H. U., a white girl about 17 years old, was admitted to the ward on Jan. 21, 1939, with a complaint of pain and discomfort in her abdomen. About midnight before the day of admission she awoke very nauseated and vomited several times. The nausea continued all night and was accompanied by several loose stools. In the morning she had a temperature of 100 F. The rest of her history was entirely normal or irrelevant. The food history was irrelevant. At the time of admission she was still nauseated but had no diarrhea, vomiting or other gastrointestinal complaints. She had not eaten all day.

The patient was well developed and well nourished with no gross abnormalities. Her temperature was 98.8 F. and her pulse rate 80. Her face was flushed and the skin around the

Blood Counts in Case 3

	Total	Eosino- phils	Neutro- phils	Baso- phils	Lympho- cytes	Monoc- ytes
8:15 a. m.	6,600	4	60	0	27	10
1:15 p. m.	6,000	2	63	0	30	4
5:00 p. m.	6,200	12	61	1	19	7

eyes somewhat edematous. The throat, lungs and heart were entirely normal. Examination of the abdomen revealed some diffuse discomfort on manipulation, the tenderness being somewhat more marked in the right lower quadrant. There was no rigidity, abnormal masses or enlarged organs. Examination of the extremities revealed no muscle tenderness. The provisional diagnosis was acute gastro-enteritis or trichinosis.

The urine was normal except for a few epithelial cells. The total white count was 12,000 with 16 per cent eosinophils, 68 per cent neutrophils, 14 per cent lymphocytes and 2 per cent monocytes. The cutaneous test with trichina antigen was strongly positive. She was given 3 Gm. of tetrachlorethylene followed by magnesium sulfate two hours later.

During the next twenty-four hours her temperature varied from 99 and 101 F. By the end of the second day her temperature was normal and all the nausea and intestinal discomfort and tenderness had disappeared. She was discharged with a diagnosis of trichinosis with acute gastro-enteritis.

She returned January 30 (eight days from onset) for a check-up. She had no complaints and no abdominal or muscle tenderness. The white count was 6,000 with 3 per cent eosinophils, 57 per cent neutrophils, 36 per cent lymphocytes and 4 per cent monocytes.

CASE 3.—E. B., a white man about 21 years old, came into the clinic on Jan. 23, 1939, complaining of headache, fever, backache, pains in all his muscles, marked malaise and swollen glands in the back of the neck. All the symptoms except the muscle tenderness had been present for a week. He had eaten fresh pork one or two days before the onset. The muscle pain and tenderness had developed within the last two days. He had no complaints relative to the cardiovascular, respiratory, gastrointestinal or genito-urinary tract. No other relevant facts were obtained.

He stated that about a year before he had had an attack of a similar nature (which he called "glandular fever"). He was in the hospital for a week and was discharged with a diagnosis of trichinosis. No biopsy was made.

The patient was well nourished and well developed and acutely ill. His temperature was 101 F. and his pulse rate 95. His face was flushed and a definite edema was present in the soft tissues around the eyes. The conjunctiva was injected. The breath was foul and the tongue heavily coated. The mouth and throat, chest and abdomen were entirely normal. The muscles of the extremities were slightly tender. There was considerable posterior cervical adenopathy. He was admitted to the ward with a diagnosis of acute infection of the upper respiratory tract or typhoid.

The white count was 4,800 with 18 per cent eosinophils, 63 per cent neutrophils, 15 per cent lymphocytes and 4 per cent monocytes. The urine revealed only a trace of albumin. Agglutination tests for typhoid, paratyphoid, undulant fever and tularemia were all negative. The cutaneous sensitivity test with trichina antigen was very strongly positive. He was given 3 cc. of tetrachlorethylene followed by magnesium sulfate two hours later.

He was quite ill for the next forty-eight hours, his temperature going as high as 104 F. By the end of the third day, however, the headache and muscle pains had definitely improved. A white count showed 9,000 cells with 29 per cent eosinophils and 55 per cent neutrophils. The next day the patient had no complaints, although his face was still swollen and his temperature from 99 to 100.5 F. The white count was still 9,000, but the eosinophils had increased to 36 per cent. He left the ward without permission, as he wanted to go home and rest.

On February 1, nine days after the first admission, he returned to the clinic for a check-up. He still had some muscle soreness and tenderness and complained of moderate malaise and slight undulating fever. He had been in bed throughout his absence. The white count was 6,100 with 36 per cent eosinophils, 40 per cent neutrophils, 24 per cent lymphocytes and 2 per cent monocytes.

On February 8 he seemed to be almost symptom free. Owing to a disagreement with our blood counts and the data of another laboratory, three counts were made the same day.

The last check-up was on February 25, about five and one half weeks after the onset. At that time he was symptom free. The white count was 6,500 with no eosinophils, 60 per cent neutrophils, 36 per cent lymphocytes, 1 per cent basophils and 4 per cent monocytes. The count was taken in the morning.

CASE 4.—J. A. C., a white man aged 22, came into the clinic on Jan. 24, 1939, complaining of severe headache, marked malaise, fever, abdominal discomfort and some aching in the back and legs. He was perfectly well until the previous night. The illness began with abdominal discomfort followed by the other symptoms. He believed he had a slight fever, but there were no chills. To his knowledge he had had no previous attacks. The food history was entirely irrelevant. The respiratory, cardiovascular, gastrointestinal and genito-urinary systems were essentially normal except for mild chronic constipation. The appendix had been removed several years previously.

The patient was well developed and well nourished and appeared ill. His temperature was 100.5 F. and the pulse rate 88. The skin was warm and dry and the face flushed. There was some suggestion of edema around the eyes. A small amount of tenderness was found over the frontal sinuses, but the head and neck were otherwise normal. The chest was entirely normal. No pathologic abdominal condition was found except a tender palpable colon filled with feces. The muscles of the back and extremities exhibited no tenderness. He was admitted to the ward with a tentative diagnosis of acute infection of the upper respiratory tract and fecal impaction.

An enema gave excellent results. The next morning he was greatly improved. The urine was normal but the blood count revealed 5,000 white cells with 8 per cent eosinophils, 68 per cent neutrophils, 24 per cent lymphocytes and 2 per cent monocytes. He preferred not to take a vermifuge, and since he was symptom free he left the ward late in the afternoon of the second day. Material was not available for a cutaneous test. He left school a few days later and no follow-up was possible. He even refused to return for another blood count. In view of the blood count and the similarity of the symptoms to those of the other patients in the ward at the same time, it was felt that he had suffered a mild attack of trichinosis.

CASE 5.—H. T. S., a white man aged 23, came to the clinic on Jan. 26, 1939, chiefly because of headache, fever and marked malaise. The history was that he ate a pork sandwich about three days previously. About twenty-four hours later he became ill with headache, backache, marked malaise, a low grade fever and marked abdominal discomfort. The previous night he was markedly nauseated but did not vomit. There was no diarrhea at any time. During the previous twenty-four hours the headache and backache had somewhat improved but the fever and malaise had increased. The rest of the history was entirely irrelevant except for a slight cough and tracheal irritation for the last twenty-four hours. There had been no expectoration, dyspnea or other chest complaints. He had never had any illness similar to the present one.

The patient was well developed and well nourished and he appeared ill. His skin was warm and dry and his face flushed, with definite subcutaneous edema about the eyes. The temperature was 102.2 F., the pulse rate 120 and the respiration quite rapid. Careful examination of the rest of the head, throat, chest, abdomen and genitalia was entirely negative. There was no muscle tenderness and the reflexes were normal. He was admitted to the ward with a tentative diagnosis of trichinosis with possible early acute infection of the upper respiratory tract.

A blood count made after admission revealed 4,550 white cells, with 2 per cent eosinophils, 68 per cent neutrophils, 26 per cent lymphocytes and 4 per cent monocytes. The urine revealed only a slight trace of albumin.

The night after admission the patient became very nauseated and had a severe chill followed by a temperature of 103 F. He slept most of the rest of the night and the next morning appeared much improved. There were no respiratory complaints and the other symptoms were greatly alleviated. A new count revealed 8,450 white cells with a differential count of 26 per cent eosinophils, 56 per cent neutrophils, 16 per cent lymphocytes and 6 per cent monocytes. No material was available for a cutaneous sensitivity test for trichinosis but he was given 2.5 cc. of tetrachlorethylene followed by magnesium sulfate.

The next day his face was much less flushed and his only complaint was a slight headache. His temperature was still 101 F. with a pulse rate in proportion. By the fifth day his temperature was entirely normal and he was symptom free. He was discharged, the final diagnosis being trichinosis.

On Feb. 7, eight days after discharge, he returned for a check-up. He was entirely well. The white count was 5,850. The differential count revealed no eosinophils or basophils, 60 per cent neutrophils, 32 per cent lymphocytes and 8 per cent monocytes.

CASE 6.—On Jan. 30, 1939, F. D. S., a white man aged about 20, came in complaining only of marked malaise. He had been perfectly well until the previous day, when he began to feel "rotten all over." A slight headache also developed, and during the night he had several chills and a continuous fever. He also had a slight irritation of the throat and some burning of the eyes. At the time of admission the only remaining complaint was the marked malaise and a slight headache. There were no other eye, nose, throat or respiratory complaints, and the cardiovascular, genito-urinary and gastrointestinal histories were entirely noncontributory. He stated that he ate some type of bologna meat the day before the onset but that there had been no other meat in his diet since he ate beef a week previously. He had had no previous attacks.

The patient was well developed and well nourished and appeared ill. His skin was hot and dry and his face red, with considerable edema around the eyes. The conjunctiva was slightly injected and the pharynx slightly reddened. Moderate cervical adenopathy was present. The rest of the examination was entirely negative. There was no muscle tenderness. His temperature was 102 F. and his pulse rate 110. The blood pressure was 125 systolic, 84 diastolic. The provisional diagnosis was trichinosis.

The urine analysis was essentially negative. The white count was 12,500 with 8 per cent eosinophils. The cutaneous sensitivity test with trichina antigen was positive. Three cc. of tetrachlorethylene was given by mouth followed by magnesium

sulfate. The next day his temperature had dropped to 99 F. The patient felt so much improved that he left the ward without permission before a second count could be taken.

On February 7 (nine days after the onset) he returned for a check-up. He had no complaints or relevant physical evidence. A count revealed 5,000 white cells with 4 per cent eosinophils, 66 per cent neutrophils, 24 per cent lymphocytes and 6 per cent monocytes.

CASE 7.—On Jan. 30, 1939, Miss R. W., aged about 20, white, came to the clinic complaining chiefly of nausea and occasional headaches for the last two days, together with a marked malaise. She ate pork sausage and pork chops the day before the onset. (The chops were well done.) There were no symptoms relative to the head, neck, cardiovascular or respiratory system. There were absolutely no other abdominal complaints. The bowels and stools had been entirely normal. Her appetite had been poor since the onset of the present illness. The patient gave a history of chronic sinusitis and hay fever, but there had been no recent attacks. She had been working very hard in school for the last four weeks.

The patient was well developed and well nourished and she appeared definitely ill. Her temperature was only 99 F., but her pulse rate was 96. The skin was warm and dry with flushing of the face and a suggestion of edema about the eyes. The rest of the head, the chest and the abdomen were entirely normal. The blood pressure was 116 systolic, 80 diastolic. She was admitted to the ward with a tentative diagnosis of overwork and exhaustion and possible trichinosis.

A white count revealed 10,500 white cells with 2 per cent eosinophils, 72 per cent neutrophils, 24 per cent lymphocytes and no monocytes. The urine was normal.

That night she had a large bowel movement which appeared to give symptomatic relief. The temperature remained around 100 F., however, with a rapid pulse. A new count revealed 12,250 white cells with 11 per cent eosinophils, 78 per cent neutrophils, 9 per cent lymphocytes and 2 per cent monocytes. She was given 2.5 cc. of tetrachlorethylene followed by magnesium sulfate.

The next day, February 1, she was greatly improved symptomatically with a normal temperature. A new blood count revealed only 5,950 white cells with 7 per cent eosinophils, 77 per cent neutrophils, 13 per cent lymphocytes and 3 per cent monocytes. She was discharged that evening. No material was available for a cutaneous sensitivity test. The final diagnosis was trichinosis.

On February 8, seven days after discharge, she returned for a check-up. She was symptom free and the white count was 5,000. (The slides for a differential count were accidentally destroyed.)

CASE 8.—On Jan. 31, 1939, D. S. K., a white man aged about 21, came in complaining chiefly of nausea and marked malaise. He was perfectly well the previous day, and in the evening he had eaten rather copiously of a pork roast (his work consisted of kitchen duties), some parts of which were definitely underdone. The symptoms all appeared the next morning. In addition to nausea and malaise, he had a slight frontal headache and some vague abdominal discomfort. He had one loose stool shortly after the appearance of the symptoms but no vomiting at any time. He also had had a slight amount of aching of the back, legs and arms since the onset and also a low grade fever but no chills. There were no other complaints relative to the head, cardiorespiratory, gastrointestinal or genito-urinary tract. The past history was essentially noncontributory.

The patient was well developed and well nourished and looked quite ill. His temperature was 99.8 F. and his pulse rate 100. There were no gross defects or deformities. The skin was warm and dry. The face was flushed, with slight edema of the subcutaneous tissues about the eyes and nose. The head and throat were otherwise normal. There were no abnormal features in the chest or abdomen (not even increased tenderness). A small amount of tenderness of the muscles of the calf, biceps, shoulder and lumbar area was present. He was admitted to the ward with a tentative diagnosis of trichinosis or acute gastro-enteritis.

A blood count revealed 11,500 white cells, with 8 per cent eosinophils, 74 per cent neutrophils, 14 per cent lymphocytes and 4 per cent monocytes. The urine was normal. He was given 3 cc. of tetrachlorethylene followed by magnesium sulfate.

During the night his temperature went to 101.2 F. and his discomfort increased. In the morning his temperature was normal and he looked greatly improved. He had no complaints. A cutaneous sensitivity test with trichina antigen was strongly positive. A new blood count revealed 12,000 white cells with 14 per cent eosinophils. He was symptom free the next day and was discharged. He failed to return for a check-up but remained perfectly well.

CASE 9.—On Feb. 9, 1939, Miss H. B., aged 19, white, consulted us at the clinic because one of our previous patients had come from her sorority. Her only complaints were malaise and some abdominal discomfort for the last forty-eight hours. She had eaten fresh pork forty-eight hours before the onset of the symptoms. The rest of her past history was entirely irrelevant.

The patient was well developed and well nourished and was not acutely ill. The pulse and temperature were normal. There were no gross abnormalities. The face was slightly flushed but there were absolutely no other abnormal features. The chest and abdomen were entirely normal and there was no muscle tenderness.

A count revealed 5,600 white blood cells with 5 per cent eosinophils, 78 per cent neutrophils, 15 per cent lymphocytes and 2 per cent monocytes. She refused to stay in the hospital and left before the count was completed.

She returned the next day and received a cutaneous sensitivity test to trichina antigen. The test was definitely positive. A new count revealed 6,000 white cells with 14 per cent eosinophils, 68 per cent neutrophils, 14 per cent lymphocytes and 2 per cent monocytes. She stated that her symptoms had not changed. She was given 2.5 cc. of tetrachlorethylene by mouth followed by magnesium sulfate. She was in the ward only about six hours. The final diagnosis was trichinosis.

On February 8, six days after her discharge, she returned for a check-up. The white blood count was 7,200. The differential count was reported as unsatisfactory but there was no eosinophilia.

CASE 10.—On Feb. 4, 1939, L. A., a white man aged about 20, came to the clinic complaining chiefly of abdominal pain and discomfort. His illness began about six days previously and first consisted of marked malaise, anorexia and a "heavy feeling." Two or three days after the onset he began to have a mild headache. There were no chills, but he felt that he had a low grade fever at times. He had been trying to play tennis at intervals and his muscles were all sore (from this?). For a week he had had considerable difficulty in reading accompanied by some dull aching around the eyes. He had eaten pork (pork chops) twice in one day about twenty-four to thirty-six hours before the onset of the present illness.

The rest of the history was irrelevant. He had had no constipation, diarrhea, vomiting, abnormal stools, jaundice or other abdominal complaints. (His abdominal complaint was not actual pain but diffuse discomfort.) He had no chronic diseases. There was no history of sinusitis or error of refraction.

The patient was well developed and nourished and there were no gross deformities. His temperature was normal but his pulse rate was 96. The face was flushed and there was a definite circumorbital edema. No tenderness or other pathologic feature was noticed in the sinuses, and the rest of the head was entirely normal. The chest was normal. The abdomen showed only a diffuse tenderness, with no enlarged organs, masses or rigidity. There was definite tenderness of the muscles of the extremities and back. He was admitted to the ward with a tentative diagnosis of trichinosis.

A blood count revealed 10,000 white cells, with 8 per cent eosinophils, 60 per cent neutrophils, 28 per cent lymphocytes, 2 per cent basophils and 2 per cent monocytes. The urine was normal. A cutaneous sensitivity test with trichina antigen was positive. He was given 3 cc. of tetrachlorethylene followed by magnesium sulfate. The next morning his temperature was still normal. The abdominal discomfort was gone, likewise

the tenderness. The aching of the muscles was unchanged. He was allowed to go home and stay in bed.

February 9 (four days later) he returned for a check-up. He had no complaints and most of the muscle tenderness had disappeared. A count revealed 6,400 white cells with 3 per cent eosinophils, 56 per cent neutrophils, 33 per cent lymphocytes and 8 per cent monocytes. On February 25 he came in with malaise (apparently from an acute infection of the upper respiratory tract). His count revealed 6,400 white cells with 3 per cent eosinophils and 70 per cent neutrophils. The final diagnosis of his previous condition was trichinosis.

COMMENT

In studying the cases just presented one easily notes the similarity of the symptoms in all cases. In nearly every instance the onset was chiefly characterized by a marked malaise with some abdominal discomfort. Nausea was usually present, but diarrhea and vomiting were usually absent. Some degree of fever was present in nearly every case, and chills in some. Only in cases 3 and 10, in which (especially the former) the stage of larval migration was being entered, was there any complaint of muscle pain or tenderness. In only one case was there no history of eating pork from one to three days before the onset, and in several cases the pork was not well cooked.

Examination of the patients revealed several noteworthy points: First, the patients all looked and acted quite ill; second, a definite flushing of the face with some degree of edema about the upper part of the face was present; third, all but one complained of generalized discomfort when the abdomen was palpated. The temperature was usually not high. In the two with more advanced infestation (patients 3 and 10, especially the former), muscle tenderness was present.

In all cases in which tests were made there was a positive reaction to the intracutaneous injection of trichinella antigen.² A control test of physiologic solution of sodium chloride was used with every injection. This test was negative or nearly so on the first day of the onset but was definitely positive in all cases by the third day. In case 3 (showing signs of muscle invasion) there was an area of edema and erythema about 4 inches in diameter.

The total white counts were normal or but slightly increased. Eosinophilia was usually not present until the second day after the onset. In the cases treated within the first few days of the illness, all symptoms disappeared within two to four days and the counts were normal within ten days; furthermore, no muscle tenderness developed. Biopsies were requested but refused in every instance. Blood serum from patient 3 was sent to Washington for a precipitation test, but unfortunately the container was broken in transit. Fecal studies revealed no evidence of parasites.

Owing to the fact that no biopsies were made, we cannot definitely say that the cases reported were trichinosis; however, the epidemic-like grouping of the cases, the positive cutaneous reactions, the eosinophilia, the history of eating pork (partially cooked in some instances) and the absence of any other similar condition makes it seem highly probable that trichinella infestation was the cause of the symptoms observed. The symptoms in every case were similar, and all patients appeared within an interval of about ten days, many being in the wards at the same time.

In order to be more certain about the value of the positive skin test, injections were made in a large

2. This was obtained from the National Institute of Health, U. S. Public Health Service, Washington, D. C.

number of cases of sinusitis, gastro-enteritis and other diseases during the next three months. All reactions were entirely negative. Furthermore, no cases of eosinophilia were observed during this time.

It is our belief that the sudden, almost simultaneous, appearance of the entire group of cases was due to a shipment into Tucson of "measly" pork. As soon as the dining halls were advised of the presence of the infestation on the university campus, no more pork was served for over a month; also no more cases developed.

We cannot say that the administration of tetrachlorethylene stopped the progress of the disease. It is possible that the cases so treated were so mild that recovery would have occurred spontaneously with no further symptoms. However, the appearance of muscle pain and tenderness in the two cases in which we were consulted about a week after the onset, and the long drawn out course of case 3, make us believe that the drug actually stopped what may have turned out to be severe infections, preventing the appearance of the second and third stages of the disease.

One further point previously unmentioned is the peculiar tendency for the eosinophil count to increase during the day (in the case of marked muscular involvement). Counts were made on several successive days to verify this. It would appear that muscular action during the day must liberate the foreign protein from the muscles and stimulate the production of the eosinophils. If this change exists in every case, differential counts had best be made at the close of the day.

SUMMARY

1. Of ten patients believed to have been infested with *Trichinella spiralis*, all but one gave a history of eating pork from one to three days before the onset.
2. The condition of eight of these patients was diagnosed within the first three days of the onset. The most common symptoms were malaise, abdominal discomfort, fever, headache, and edema around the eyes. All showed a definite eosinophilia and all tested gave a positive skin reaction with trichinella antigen. Administration of tetrachlorethylene was followed by complete and immediate recovery.
3. The two patients consulting us six and seven days after the onset contracted muscle pain and tenderness; patient 3 showed a fairly long drawn out convalescence.
4. The eosinophil content of the blood was shown to rise continually during the day, being highest in the evening.

Bence Jones Protein.—Bence Jones protein is chemically and immunologically distinct from the other serum proteins. From the work of Meyler it would seem to be a normal constituent of bone marrow, lymphocytes and other white blood cells. A source of Bence Jones protein exists, therefore, under normal conditions and an increase may be expected when large numbers of white cells are destroyed as in empyema or leukemia, or when bone marrow gets into the circulation, as in bone metastases. Nevertheless, even under these conditions, Bence Jones proteinuria occurs very infrequently, which may mean that the body is capable of utilizing or destroying relatively large amounts of this protein. It is only when the amounts produced are excessive and not completely destroyed that a part is excreted in the urine. The excretion of Bence Jones protein is known to have exceeded 50 Gm. per day in several instances. When the quantity excreted is large and of long duration, anatomical injury to the kidneys may be assumed.—Bodansky, Meyer, and Bodansky, Oscar: *Biochemistry of Disease*, New York, Macmillan Company, 1940.

VASCULAR DISORDERS OF PERIPHERAL NERVES

J. L. FETTERMAN, M.D.

AND

D. K. SPITLER, M.D.

CLEVELAND

Medical literature has considered instances of peripheral nerve involvement occurring in the course of specific diseases. Yet the concept of neuropathy due to a defective blood supply has not been sufficiently stressed.¹ Recent experience in the wards of Lakeside Hospital with ischemic neuropathy has prompted us to assemble clinical examples which have occurred in a variety of diseases and to group them together under one heading.

ANATOMY

The standard textbooks of anatomy and histology give but brief mention to the vascular supply of peripheral nerves. Ramage² observed that, in the nerve trunks, cords and peripheral nerves of the upper extremity, circulation is maintained through several nutrient arteries. His work substantiates the theory laid down by Quénu and Lejars³ that the blood supply of a peripheral nerve does not come from a single arterial branch but always comes from multiple sources.

Buitink⁴ studied the blood supply of the peripheral nerves in the lower extremity. He determined that it arises from neighborhood vessels, branches of which enter the nerve at various angles and then subdivide into ascending and descending branches. Twigs from these vessels frequently anastomose, providing a network which can be seen in the gross view. Chaumet⁵ has confirmed these observations by roentgenograms of injected specimens. In view of this anastomosis and the free communication of the arterial twigs within the nerve trunk, a nerve lesion of clinical degree could occur only if many twigs in one area were simultaneously affected or if a main branch was occluded. Under the circumstances of a severe diminution in the blood supply there would be a consequent degeneration of the nerve trunk at this level and in that portion of the nerve distal to the site of ischemia. An excellent description of the degenerative changes which follow damage to a peripheral nerve is contained in Hassin's book on neuropathology.⁶

Among the clinical conditions in which damage to peripheral nerves occurs because of vascular disease, the following may be mentioned:

1. Trauma.
2. Embolism.
3. Arteriosclerosis and diabetes mellitus.
4. Thrombo-angiitis obliterans (Buerger's disease).
5. Periarteritis nodosa.
6. Syphilis.
7. Polycythemia vera and other miscellaneous causes.

Dr. J. T. Roberts collaborated, particularly in the matter of several injection and dissection experiments.

From the Medical (Neurologic) Division, Lakeside Hospital, and the Western Reserve University School of Medicine.

TRAUMA

Chemical Arterial Injection.—Our concern is not with the ordinary mechanical injuries to peripheral nerves. This subject is well known as the result of civil and wartime injuries and has received adequate presentation, especially in the monograph of Pollock and Davis.⁷ We wish rather to call attention here to a rare lesion caused by trauma to the vasa nervorum. Gammel⁸ reported an instance in which a 48 year old man complained of pain in the foot following an intragluteal injection of bismuth and potassium tartrate. The patient complained of pain radiating from the hip to the sole of the foot and experienced difficulty in raising the ankle. A neurologic consultation by one of us (J. L. F.) revealed a paralysis of the peroneal muscles and diminution of sensation on the dorsolateral aspect of the foot. In the region of injection there was bluish discoloration of the skin of the buttocks. Gammel interpreted the condition as due to an injection into the inferior gluteal artery, which supplies an area of the buttock and also sends a branch to the sciatic nerve (arteria comitans nervi ischiadici). This theory was confirmed by a second case reported by Gammel.⁹ This patient had also received a bismuth injection into the buttock, developed pain in the foot and showed evidence of a paralysis of the calf and intrinsic foot muscles due to involvement of the tibial branch of the sciatic nerve. In this case a biopsy of the skin and subcutaneous tissue revealed bismuth crystals in the vessels and marked inflammatory reaction in the perivascular tissues. Gammel's paper calls attention to similar cases reported by Freudenthal.¹⁰

EMBOLISM

An embolus traveling in the blood stream is a source of danger to the region of the body where it lodges. Fortunately the occurrence of recognizable embolic lesions in peripheral nerves is rare. Large emboli which occlude the main artery to a limb obviously cause more extensive damage than the mere ischemia of peripheral nerves, yet many of the symptoms and signs are explainable by the concomitant neuropathology. Scupham and de Takats¹¹ state "Locally, the characteristic findings are pallor, decreased cutaneous sensation, loss of heat, reduction or absence of reflexes, and paralysis."

McKechnie and Allen¹² have analyzed 100 cases of embolism and thrombosis of the peripheral arteries. Regarding ischemic neuropathy they have written "In cases in which sudden arterial occlusions do not lead to gangrene, the symptoms due to sudden occlusions may merge imperceptibly into those of ischemic neuritis. The pains tend to be paroxysmal and severe and to cover large areas which do not correspond to any definite nerve distribution. They may persist for weeks or months."

Collier,¹³ in his Morison lecture on peripheral neuritis, in discussing neuritis observed during the course of

fevers, stated that ". . . in very many of the cases the clinical picture was that of an isolated lesion of one peripheral nerve trunk, such as could be caused by a local settling of typhoid bacilli or by a vascular lesion. . . . The syndrome has not the aspect of a direct toxic neuritis. It may occur in many febrile conditions and not infrequently in pneumonia toward the crisis, and in this latter condition Hughlings Jackson was in the habit of referring it to a relative asphyxia of the lower nerve elements." Further in this essay, in discussing a type of diabetic neuropathy, he writes "The second variety, much less known and much more serious, is the rapid and painless onset of complete and irrevocable paralysis of one or more large peripheral nerve trunks . . . which was a thrombosis of the artery supplying the nerve trunk. . . ."

We have encountered embolic lesions of peripheral nerves infrequently. However, about a year ago we met this complication in an elderly Negro who was convalescing from type III pneumococcus pneumonia with bacteremia. Several days after the crisis he suddenly complained of inability to move his foot. A neurologic examination showed a loss of power of the peroneal muscle group and of the dorsiflexors of the foot. The muscles in the calf functioned well. There was an area of numbness over the outer portion of the dorsum of the foot. The sudden onset of complete loss of function of the peroneal nerve in a patient who had septicemia is best explained by the occurrence of an embolus to the nutrient artery of this nerve.

Tinel¹⁴ mentioned several instances of neuritis and neuralgias of apoplectiform origin. It was his view that tiny hemorrhages might occur in the posterior nerve roots as the result of straining or lifting and thus produce symptoms of radiculitis. He pointed out that the symptoms were neuralgic and had no motor components. He cited two case histories, in one of which there was xanthochromic spinal fluid.

ARTERIOSCLEROSIS AND DIABETES MELLITUS

In Critchley's¹⁵ lecture on "The Neurology of Old Age," several interesting observations are recorded relative to data on older persons which might be considered seriously abnormal in the younger age group. Sensory complaints such as stabbing, darting or aching pains and dysesthesias, particularly in the lower limbs, are quite common. Frequently there is a diminution in the vibratory sensibility, sometimes amounting to almost total loss of this sensation. The author refers to Pearson,¹⁶ who found that there is a slight diminution in sensibility over the lower extremities, which becomes more noticeable decade by decade and may be pronounced after the age of 50. Likewise, appreciation of tactile and painful stimuli may be impaired or even lost. The tendon reflexes tend to become sluggish and may be difficult to elicit. "So frequently does this occur, in the absence of other neurological manifestations, that one is driven to the conclusion that absence of an ankle jerk in old age is without pathological significance." Critchley concludes that changes at all levels may play a role and that the impaired touch sensation is best explained by ". . . changes in the peripheral nerves, probably in the nature of senile or arteriosclerotic polyneuritis." Priestley¹⁷ made histologic studies of the

peripheral nerves removed from the amputated extremities in six cases of arteriosclerotic gangrene. He reported “. . . wallerian degeneration and fibrosis,” more marked distally and appearing to be in direct ratio to the amount of arteriosclerosis. In a study of 280 cases of thrombo-arteriosclerosis obliterans, Hines¹⁸ found ischemic neuropathy in twenty-two, or 8 per cent.

Diabetic “neuritis” has been interpreted differently for many years. Recently there has been a general tendency to consider it, at least in a large number of cases, as an ischemic neuropathy in which arteriosclerosis is a fundamental factor (Sandstead and Beams,¹⁹ Needles,²⁰ Grinker,²¹ Woltman and Wilder²²). Clinically it is a painful neuropathy, with varying degrees of hyperesthesia and often extreme cutaneous tenderness (frequently worse at night). The distribution is over the distal portions of the legs and sometimes the forearms. It is uncommon under 40 years of age. Jordan²³ made an extensive review of 226 selected cases of diabetes mellitus with neuritic manifestations, of which seventy-two belong to the degenerative or circulatory type. These occurred in patients over 40 years of age and were accompanied by arteriosclerosis. The condition was usually progressive over a long period of time, although in some instances there was improvement. Woltman and Wilder²² studied the spinal cord and peripheral nerve changes in ten cases of diabetes mellitus. They found degenerative changes in the spinal cord, which were milder than the changes in the peripheral nerves. In nearly all cases there was a thickening of the walls of the intraneural vessels. They conclude “. . . that the factor of greatest significance in the nerve lesions of diabetes is atherosclerosis.” Collier¹³ expressed a similar view: “. . . since the nerve trunk paralysis is only met with in people who are well above middle age, it is probable that atherosclerosis and the linear calcification of the arteries commonly occurring in diabetes is the fundamental cause of the sudden and final destruction of the large nerve trunk.”

Recently Sandstead and Beams¹⁹ found that the oral administration of sodium chloride to diabetic patients suffering with pain of neurocirculatory origin both relieves the pain and improves peripheral circulation (as was measured by the histamine reaction). They write “. . . this suggests that ischemia, the result of vascular disease, may be the cause of neuritic symptoms.”

Because vitamin deficiency has been considered the etiologic agent in diabetic “neuritis,” Needles²⁰ studied the vitamin B intake of three patients with this complication of diabetes mellitus. In each he found the vitamin/calory ratio above the required figure and concluded that it was perhaps due to vascular changes in the nutrient arteries to peripheral nerves.

THROMBO-ANGITIS OBLITERANS

Pain and its control is one of the major concerns of the physician when confronted with a patient suffering from thrombo-angiitis obliterans. Since this clinical entity was first described by Buerger in 1917 the eti-

ology of the pain has been the subject of speculation and research. Buerger²⁴ felt that the pain was due to a fibrosis about the nerve trunks which accompanied diseased vessels.

Brown, Allen and Mahorner²⁵ comment on the increase in perineural connective tissues and also on degenerative changes in the smaller nerves of the toes. They suggest the possibility of long standing ischemia, “approaching the threshold of tissue death” as the cause of these latter changes and of the pain. In a study of amputated extremities, Meleney and Miller²⁶ found complete occlusion of the vasa nervorum in half of the cases. In a clinical correlation these authors state that in every instance there was a history of excruciating pain. They state, however, that there were several patients who suffered severe pain in whose nerves no arterial occlusion was found. (It is possible that the occlusion might not have been discovered or have been the result of partial occlusion of a main arterial trunk.) Goldsmith and Brown²⁷ analyzed the cause of pain in 100 cases of thrombo-angiitis obliterans and considered that ischemic neuritis was present in twelve of that group. A recent contribution by Barker²⁸ consisted of the study of the nerves in seventeen amputated extremities from patients suffering from thrombo-angiitis obliterans. He reported an increase in the perifascicular and intrafascicular fibrosis. Patchy wallerian degeneration, diseased, coiled up and swollen axis cylinders, and some edema and atrophy were seen. Barker did not believe that these changes were due to obstruction of the vasa nervorum but was of the opinion that the nerve lesions came from ischemia as a result of the extensive occlusion of the main arterial trunks. In all cases in which “neuritic” pain occurred there was definite wallerian degeneration of nerves. The lesions were more pronounced than those described by Woltman and Wilder²² in diabetes and by Priestley¹⁷ in the arteriosclerotic group.

SYPHILIS

The role of the vascular changes in syphilis is too well known to require emphasis (Osler,²⁹ Boyd³⁰). Warthin³¹ has devoted considerable attention to the frequency of syphilitic periarteritis, panarteritis and arteritis obliterans of smaller arteries and believes that these occur to a greater or lesser degree. Herrmann³² has described the various types of syphilitic arteritis of the extremities. Sézary³³ has covered the subject of neurosyphilis and stressed the frequency of arteritis as a cause of neurologic manifestation.

Involvement of peripheral nerves in syphilis is not common but has been described. Margulis³⁴ and Papow³⁵ have reported cases of syphilitic neuritis in which pathologic studies showed infiltration of the walls

of the vasa nervorum with plasma cells and lymphocytes, resulting in endothelial thickening. Hassin⁶ mentions the occurrence of syphilitic neuritis. Recently Simon and Berman³⁶ have discussed this subject with thoroughness and reported a case illustrated by photomicrographs. These pictures show unmistakable marked obliterative endarteritis and perivascularitis. They state "Syphilitic polyneuritis may occur in all stages of syphilis and its occurrence is not limited to the early stages. The fundamental pathologic process is panvasculitis, with lymphocytic and plasma cell infiltration in and about the walls of the blood vessels, associated with intimal proliferation, leading to obliterative endarteritis and endophlebitis."

PERIARTERITIS NODOSA

Periarteritis nodosa has neuritic manifestations. The symptom complex of Meyer³⁷ is often quoted: "Chlorotic marasmus, polyneuritis, and polymyositis symptoms . . ." Writers on this subject have placed the incidence of peripheral neuritis at from 20 to 40 per cent (Arkin,³⁸ Curtis and Coffey,³⁹ Kernohan and Woltman⁴⁰). This arterial disease progresses through stages of degeneration, inflammation, granulation and finally fibrosis. Throughout this course thrombosis may occur, resulting in anemia of the organ supplied by such vessels. Ischemia is more apt to occur during the last stages, at which time there are mantles of scar tissue about the arteries. Arkin³⁸ and Kernohan and Woltman⁴⁰ have reported a series of cases in which there was definite peripheral nerve degeneration, proved at autopsy, caused by vascular lesions.

At the Lakeside Hospital, in the service of Dr. J. T. Wearn, there was a white man aged 32 who had entered the hospital complaining of migratory joint pains. Several months later there was a sudden left-sided hemiplegia. On this admission there were pallor, fever and left hemiparesis. This paralytic condition improved gradually and the patient regained the power of the left arm and leg.

On the tenth hospital day he complained of burning pain over the right foot. A day or two later there was weakness in the extension of the toes. Later there was complete paralysis of the dorsiflexors of the foot and of the peroneal muscles. The condition was a typical peroneal paralysis. This paralysis remained unchanged throughout the subsequent course of forty-two days. During this time there were pains in other extremities but no definite evidence of a peripheral nerve lesion. The autopsy (limited to the trunk) confirmed the earlier biopsy reports of periarteritis nodosa. It is very likely that the vessels in the peroneal nerve were gradually obstructed by this disease process.

POLYCYTHEMIA AND MISCELLANEOUS STATES

In polycythemia vera a number of factors are present which predispose to impaired local circulation and to thrombosis. These include an increased blood volume due to the increase in the red cells, decreased circulating minute volume and an increased blood viscosity (Harrop,⁴¹ Haden⁴²). Polycythemia vera is usually accom-

panied by marked arteriosclerosis and also capillary and arteriolar thickening and fibrosis (Reznikoff and Foot⁴³). Most observers who have written on the clinical aspect of polycythemia vera have called attention to the frequent paresthesias and neuritic-like manifestations.⁴⁴ These usually consist of shooting pains and burning sensations in the extremities. The cause of these pains varies from patient to patient, for the lesion may occur at any point between the receptor organs in the skin and the sensory cortex in the cerebrum. There may be stasis in the surface capillaries and venules, which could account for the paresthesias. Interference with the cerebral blood flow, as reported by Christian,⁴⁵ may account for certain of the sensory symptoms.

At the Lakeside Hospital a patient with polycythemia has been studied over a period of years. During his various visits he complained of shooting pains radiating from the medial aspect of the right thigh to the foot. At the first admission the reflexes were intact. Later there was hyporeflexia, which progressed to areflexia in both lower extremities. It is suggested that the circulatory change may explain these evidences of neuritis.

Other types of arterial disease have been associated with neuropathy. Barker and Brown⁴⁶ reported a case of progressive disseminated obliterating arteritis in which wrist drop and partial paralysis of the peroneal nerves of both legs were present. Barker and Baker⁴⁷ reported a case of proliferative intimitis with symptoms of peripheral neuritis and recurring necrotic ulcers of the skin. At autopsy the peripheral nerves showed perineural and intraneural fibrosis and patchy loss of myelin sheaths. The vasa nervorum exhibited the same changes (proliferative intimitis) as did arteries and veins elsewhere in the body.

We observed manifestations of ischemic neuropathy in a patient whose illness was diagnosed as proliferative intimitis. He was a man aged 49 who gave a four day history of excruciating pain in the muscles of the forearms, hands, calves and feet. There was a marked tenderness to palpation of muscles in these areas. During his hospital stay the left patellar and achilles tendon reflexes disappeared and there was a marked diminution in sensation over the distal third of the foot. Because of the pain and early gangrene of the tips of the toes, amputation of this leg was carried out. The histologic picture included endarteritis obliterans with peripheral nerve changes consisting of edema and loss of myelin. When the patient was seen a year later he complained of intermittent stabbing pain and burning in the right leg, symptoms temporarily relieved by such vasodilators as glyceryl trinitrate and amyl nitrite.

COMMENT AND CONCLUSION

This study indicates that in vascular disease, from whatever cause, peripheral nerve lesions may result with ischemia of nerve tissue as the common etiologic factor. As the causes of vascular pathologic changes are numerous, so the peripheral nerve lesions have been classified under several main headings. We have found such neuropathy in trauma, embolism, arteriosclerosis, Buerger's disease, syphilis, periarteritis nodosa and other states. Involvement of the main arterial trunk to a nerve or the simultaneous lesions in smaller branches and twigs is responsible for such ischemic changes in the nerve.

The local symptoms in each case depend on the nerve involved, the extent of pathologic alteration and the general status of the individual. Treatment should be directed toward the underlying pathologic process as well as to the symptomatic relief of the particular nerve lesion.

INCIDENCE AND INTERPRETATION OF
DIABETIC-LIKE DEXTROSE
TOLERANCE CURVES

IN NERVOUS AND MENTAL PATIENTS: A STUDY
OF SIXTY-NINE SUCCESSIVE ADMISSIONS
PRELIMINARY REPORT

G. WILSE ROBINSON JR., M.D.

AND

PRIOR SHELTON, M.D.

KANSAS CITY, MO.

The relationship between disorders of the nervous system and the metabolism of the human organism has been the subject of much clinical and experimental study. The discovery of a carbohydrate catalyst, insulin, in 1923 made it possible for Sakel in 1933 to publish his revolutionary monograph on the treatment of schizophrenia with hypoglycemic shock induced by insulin. Appel, Farr and Marshall,¹ Bennett and Semrad,² Ziskind and Somerfeld-Ziskind³ and others have reported beneficial effects from the use of small doses of insulin in various psychotic reactions of both the functional and the organic reaction types. We have observed beneficial effects from small doses of insulin and a high carbohydrate intake on such conditions as mild schizophrenia, psychoneurosis, chronic alcoholism, delirium tremens and arteriosclerotic conditions. We have reported on the use of insulin in the treatment of delirium tremens,⁴ confirming the reports of Klemperer,⁵ Puyuelo Salinas⁶ and others. We have also reported

on the use of insulin as a sedative,⁷ following the original work done by Wegierko.⁸

Sakel⁹ reported on the value of insulin in aiding in the withdrawal of morphine, and his observations have been verified numerous times in this country. While these clinical applications of insulin in nonshock doses were being studied, we were simultaneously investigating the effect of intravenous dextrose (10 per cent) in the various delirious phenomena, especially the so-called confusional states of old age.¹⁰ This work has been confirmed by Larson and his associates,¹¹ who showed that the nutritional effect of the dextrose was the real beneficial agent and that the benefit was not due to the fluids which overcome the general organism dehydration or the hypertonic effects of hyperglycemia, which reduces cerebral edema. The dextrose provides needed nourishment, generally and locally, thereby correcting certain metabolic disturbances and reversing certain secondary pathologic states in the brain.

Insulin is the activating carbohydrate metabolism hormone, and intravenous dextrose in 10 per cent solution is the most effective way to provide the patient who is deficient in available carbohydrates with the only energy-producing food used by the brain—dextrose. Our interpretation of these mechanisms has been discussed in previous reports.¹² It seemed necessary from these observations to study our patients from the standpoint of basic physiology, to try to determine whether carbohydrate metabolism was disturbed and, if possible, how and why. It is our purpose in this paper to present a preliminary report of these studies.

We felt that the basic ability of the organism to utilize dextrose must be impaired in some way if these stimulations to carbohydrate metabolism brought about improvement in our patients. Carbohydrate metabolism is a progressive process from ingestion through absorption, storage, availability and oxidation to the usual end products of carbon dioxide and water. According to Chambers,¹³ the simplest chemical test available at this time to study the integrity of the whole mechanism is the dextrose tolerance test. We selected the four hour test, as outlined by Gradwohl,¹⁴ as our investigative method so that the reaction might be studied throughout its course. We tested specimens of urine for sugar according to the Sheftel¹⁵ method. Blood and urine determinations are made in this test after ingestion of 100 Gm. of dextrose in an aqueous solution. A fasting test is made and specimens are drawn at one-half, one, two, three and four hour intervals after a test meal. Samples of urine are collected at the same time. A normal dextrose tolerance test rises about 75 points above the fasting level in thirty minutes, falls sharply about 25 points in the next half hour and then gradually returns to the fasting level within four hours. There is no glycosuria at any time during the test. There are individual variations of this curve.

* Blood sugar determinations given in milligrams of sugar per hundred cubic centimeters of whole blood.

† Urine sugar determinations given in (a) plusses (Benedict's qualitative) and in (b) per cent (Shetel method).

‡ No specimen obtained.

Successive tests were made and from these comparisons we have been able to determine a rough estimate of the state of carbohydrate metabolism at the time of admission and the improvement in this factor during the clinical course of the patient. Normal results indicate proper absorability from the gastrointestinal tract, normal passage through the liver, which takes up some but not all of the test meal, a normal mechanism for storing the excess blood dextrose as glycogen, and a normal oxidation of the dextrose in the tissues by the cells.

Variations from the normal in the curve do not indicate which factor is disturbed but only that some factor or factors are not functioning normally and that therefore carbohydrate metabolism, viewing the mechanism as a whole, is abnormal.

The interpretation of these curves has been difficult, since clinical studies on neuropsychiatric patients from this standpoint have not been done extensively. The chief use of the dextrose tolerance test in clinical medicine has been the determination of the presence or absence of diabetes mellitus. One of the latest reviews of the subject from this standpoint has been presented by Matthews and his associates.¹⁶ They discuss the one hour-two dose tolerance test and its interpretation from the standpoint of the diagnosis of diabetes. Their comment is this: "Other causes of hyperglycemia being absent, a disturbance of the ability of the organism to prevent elevation of the blood sugar above what Hansen called a criterion of diabetes mellitus." Hansen¹⁷ used the term "optimum concentration" to designate the upper limit or blood sugar ceiling above which the blood sugar would not rise in normal individuals because of fluctuations in the activity of the regulation mechanism.

These other causes have been given but little consideration in discussions of this test in clinical literature. Diabetic and diabetic-like curves are common in nervous

and mental patients. Table 1 shows our results on sixty-nine successive admissions. The first part of the table gives those in follow-up tests, while the second part is made up of those cases on which follow-up tests could not be made.

Table 2 shows the result of our application of three different criteria of interpretation of curves from the standpoint of the diagnosis of diabetes mellitus and other accepted types of glycosuria to the results in our series.

It is hardly conceivable that this high percentage of nervous and mental patients taken as they applied for treatment should have true diabetes mellitus or permanent hypo-insulinism. Only four of these patients had a fasting blood sugar in excess of 120 mg. per hundred cubic centimeters, but according to these interpretations of the dextrose tolerance curves from 39.9 to 62.3 per cent of the patients could be considered to have diabetes. All three of these criteria are methods advanced to simplify the classic procedure so as to eliminate some of the tests.

This group of patients had a variety of treatments which included insulin and metrazol shock, intravenous infusions of dextrose, insulin in small doses for metabolic and sedative purposes, thiamine hydrochloride and general hygienic help. Only one patient received definite treatment for diabetes. She had a fasting blood sugar of more than 200 mg. per hundred cubic centimeters consistently and had been treated for diabetes a number of years before she came under our care.

The clinical diagnoses of this group of cases included schizophrenia, manic depressive types, senile psychoses, alcoholism and other addictive states. Each clinical type was represented in the groups that could be interpreted as having a diabetic type tolerance curve. In many cases follow-up tests were made after an interval of a few weeks. Table 3 shows the results of the application of the foregoing three criteria to our follow-up tests.

It will be seen that, regardless of which criterion of interpretation is used, from 25.8 to 55.5 per cent of these curves return to normal under treatment that generally is not accepted as the proper treatment for diabetes mellitus. Those patients who showed improvement in their curves invariably showed symptomatic

improvement in the psychotic manifestations which were present at the time of admission. Some of the other patients who showed little improvement in their curves showed a complete psychotic remission, but follow-up tests in the future may show some improvement in their curves.

We feel that these abnormal curves result from malnutrition. The nervous and mental patient usually goes through a prolonged period before admission when hygienic habits are poor, diets are improper and various food superstitions are followed. General metabolism is frequently poor and malnutrition is a prominent feature. Physiologists have known for some time that carbohydrate metabolism is a mechanism of many factors, not simply the biochemical interplay of dextrose and insulin. We quote the opening paragraphs of Chambers' ¹² recent comprehensive review:

Undernutrition is used in a broad sense in this paper to include complete inanition as well as the dietary deficiencies. Fasting has been recognized as a factor in carbohydrate metabolism since 1873, but the greatest expansion of the entire field

TABLE 2.—Interpretation of Tests by Proposed Criteria

	A		B		C	
	Number	Per Cent	Number	Per Cent	Number	Per Cent

(1) Not included in this interpretation.

A, according to the criteria of Exton and Rose (Diabetes as a Life Insurance Selection Problem, *Proc. A. Life Insur. M. Dir. America* 18: 252-266, 1931).

B, according to the criteria of Gould, Altschuler and Mellen (The One Hour-Two Dose Glucose Tolerance Test in the Diagnosis of Diabetes Mellitus, *Am. J. M. Sc.* 1933: 611 [May] 1937).

C, according to the criteria of Matthews, Magath, Berkson and Gage.¹⁰

has occurred in the past fifteen years. During this time the endocrine control of carbohydrate metabolism has been developed and now occupies a position of major importance. An attempt to correlate the studies of undernutrition and the endocrine research has led to the following generalizations concerning carbohydrate utilization.

The maximum utilization of administered glucose is found in the normal individual when carbohydrate has been abundantly supplied in the diet. The minimum effect is obtained in the completely depancreatized animal which excretes all of the ingested sugar in the urine. Between these extremes is a series of less sharply defined intermediate stages. As the amount of carbohydrate in the diet is diminished the glucose tolerance test indicates a decreased utilization. During complete inanition there is a progressive deprivation of the carbohydrate stores in the body and an increasingly larger fraction of the test meal is lost by excretion as the fast continues. A more drastic and exaggerated condition is seen in the animal depleted by phlorhizin glycosuria. Approaching pancreatic diabetes at the lower end of the scale are the various stages of diabetes mellitus and the endocrine disturbances involving the pituitary and the adrenal. Of the many factors exerting a controlling influence on the different degrees of carbohydrate utilization as outlined, the importance of two is apparent—the amount of carbohydrate available to the cells and the endocrine control. The former seems to predominate at the beginning of the series but is superseded by the latter toward the minimum end. The literature presented in this review will give the evidence supporting these generalizations, with particular emphasis on the nutritional condition with respect to carbohydrate.

The conception of carbohydrate metabolism outlined above is based on the measurement of the body's ability to utilize carbohydrate, as determined by its reactions for several hours after the administration of pure glucose. When a glucose test meal is ingested sufficient in amount to maintain the maximum rate of absorption from the intestines for several hours, the total heat production of the body indicates that in the normal well-fed organism only about one-quarter to one-third of the absorbed sugar can be oxidized to CO₂ and H₂O. The major portion of the remainder is probably stored as glycogen, but conversion into fat, glycolysis to lactic acid, transformation into hexosephosphate, glycerophosphate, glucosamine, or other compounds may also occur. These reactions may be observed in several ways. The method most extensively used for the study of carbohydrate metabolism has been the glucose tolerance test in which the rise and fall in blood sugar concentration are determined for several hours after the administration of sugar. This test is most useful in showing small differences in utilization. It should be remembered that the blood sugar changes reflect the rate but not the nature of glucose utilization. If the impairment is large enough, information as to the total amount utilized may be obtained from the quantitative collection of the fraction excreted by the kidney. The most direct evidence for oxidation comes from carefully conducted determinations of the respiratory metabolism sufficient in duration to yield combustion quotients when interfering changes in the body are adequately controlled (Richardson, 1929). Tissue analyses yield data concerning glycogen deposition and other methods of disposal. All of these reactions must be considered in establishing a complete picture of carbohydrate utilization. The terms "utilization" and "oxidation" have been used synonymously in some of the recent literature. This is obviously inexact in short experiments.

Lehman ¹⁸ in 1873 and Claude Bernard ¹⁹ in 1877 showed that fasting animals had a glycosuria. This condition was termed "hunger diabetes" by Hofmeister ²⁰ in 1890. Bang ²¹ showed that dextrose tolerance curves were disturbed in fasting animals, while Staub ²² showed that low carbohydrate-high fat-protein diets had the same effect. All this work has been confirmed experimentally and clinically many times.

From this background of physiologic observations it is easy to understand how neurotic, overanxious types, those who diet to lose weight, diet faddists in general or those who suffer from anorexia during physical or mental illness may upset their carbohydrate metabolism balance with depletion of reserves, suppression of secretion of body insulin and the development of toxic states from improperly metabolized fats and proteins.

Diethelm, ²³ Wittkower, ²⁴ McCowan ²⁵ and Tod ²⁶ have made reports on the disturbed dextrose tolerance found in certain abnormal emotional states and various psychotic reactions. The conclusions in the past have always been that the disturbance of the dextrose tolerance curve, signifying an abnormal utilization of dextrose, was the result of the mental condition being studied and that it had no etiologic significance. However, it is hardly necessary to point out that there is at this time no universally or even widely accepted single theory as to the "cause" of various abnormal mental reactions known as the psychoses or the neu-

roses. Therefore no factor can be ignored, whether it is psychologic, physiologic or biochemical. Relatively little is known definitely about the metabolism of the brain. Himwich and Nahum²⁷ and Himwich and Bowman and their associates²⁸ have shown that the brain in health uses only dextrose as its fuel, although in certain disease states a small amount of lactic acid may be utilized. They have further found that the metabolism of the brain is decreased in all the delirious conditions which they have investigated.²⁹ The rate of utilization of dextrose is high, amounting to about 14.6 mg. per hundred cubic centimeters or 10 per cent of all dextrose used by the body, and about 90 per cent of this 10 per cent is used by the cortical cells. Kerr and Ghantus³⁰ concluded that the brain cannot store a reserve of glycogen as can other tissue and that there must be a constant supply of sugar to the brain in order to maintain the level of free sugar so that constant, continuous, healthy metabolism may proceed. In addition to dextrose, the brain requires an adequate amount of oxygen (7.4 volumes per cent) and enzymes, and a marked variation from normal in either dextrose, oxygen or enzymes produces a pathologic condition in the brain. It is certainly not illogical to assume, therefore, that disturbed carbohydrate metabolism of the organism as a whole can and will disturb the functioning ability of the brain to some degree. It is of vital importance to determine eventually the exact place of this factor in the total picture. In the meantime, when a case with the nervous type of involvement is considered from the standpoint of therapy, this factor must be given consideration when the therapy is outlined, regardless of whether it is a primary or a secondary development.

Klemperer,⁵ Puyuelo Salinas,⁶ Robinson⁴ and others have concluded that the toxic intermediate products resulting from the disturbed carbohydrate metabolism and disturbed liver function are largely responsible for the toxic type of disorders with the subsequent delirious symptoms found in cases of acute alcoholic psychoses (delirium tremens). In those cases the disturbances of metabolism are intense and are easily determined by a wide variety of laboratory tests.

Adlersberg and Porges³¹ and Sweeney³² have shown that increased carbohydrate in the diet raises and decreased carbohydrate lessens dextrose tolerance (i. e. ability to utilize dextrose). Himsworth³³ showed that in normal, healthy men the greater the carbohydrate content of the diet the greater the sensitivity of the organism to a measured dose of insulin, indicating that a high carbohydrate diet stimulates the secretion of body insulin and increases the efficiency of dextrose metabolism and utilization. The most important clinical lesson that can be learned from these tests is that glycosuria does not necessarily indicate diabetes mellitus (permanent hypo-insulinism), and that the so-called

diabetic type curve in the dextrose tolerance test is not positive evidence of diabetes; that is, that the "other causes" are of considerable clinical importance.

It is also of clinical importance that the kidney threshold for sugar is not fixed, either for the human body in general or for the individual from time to time. In a series of investigations on patients with diabetes, Sidoni³⁴ concludes:

No apparent quantitative correspondence existed between the blood sugar and the urine sugar in a large number of patients on protamine zinc insulin . . . as observed in our studies after regular prescribed meals. Probably renal functional disturbances which frequently escape detection by laboratory or physical means, brought about by the disturbed carbohydrate metabolism, were sufficient to interfere with the excretion of sugar in such a manner as to cause a partial loss and, at times, a marked loss of quantitative relationship between the urine and the blood sugar.

Our own records contain a number of cases that have been diagnosed diabetes in the past by other physicians. These patients either "spontaneously" recovered or, having been under treatment, usually self administered for many years, did not at the time of consultation with us show any evidence of a permanent hypo-insulinism, and therefore we did not consider that they had true diabetes mellitus. Exton³⁵ reported a series of 800 cases

TABLE 3.—Changes in Curves as the Result of Therapy

	Diabetic Type: Actual, Presumptive and Latent			
	Total	Corrected	Not Corrected	No Follow-Up
Exton and Rose (A, table 2)...	40	7	11	24
Gould et al. (B, table 2).....	25	8	5	12
Matthews et al. (C, table 2)..	38	11	7	20

in which a reducing substance appeared in the urine. He found that less than 2 per cent of these patients had true diabetes mellitus. The staff members of the George F. Baker Clinic³⁶ feel that glycosuria is presumptive evidence of diabetes mellitus, although 14 per cent of 14,000 patients who entered the clinic with a diagnosis of diabetes mellitus had nondiabetic mellituria or glycosuria due to pentose, levulose and lactose in the urine.

CONCLUSIONS

1. An abnormality of dextrose tolerance is a common finding in nervous and mental patients. This indicates that there is a disturbance in the utilization of carbohydrates and that the whole metabolic function is disturbed. It may be one of the etiologic factors in abnormal nervous and mental reactions.

2. Regardless of its place in the etiologic picture, the dextrose tolerance should be corrected as quickly as possible during the general therapeutic management of the case. Only after improvement of feeling tone and general metabolism can special measures, such as shock therapy and psychotherapy be readily effective.

3. The diagnosis of diabetes mellitus in patients with a history of nervous and nervous type conditions must be made with caution, for only after a long period of observation and treatment to correct malnutrition, metabolic disturbances resulting from improper habits,

nervous tension states and other factors as yet undetermined can such a diagnosis be made.

4. The physician in general practice should keep this fact in mind when he is consulted by patients who present a symptom complex of "nervousness," fatigue and ready exhaustibility, vague somatic complaints and the picture that is usually diagnosed "psychoneurosis." If evidence of disturbed carbohydrate metabolism is found, a high carbohydrate diet with adequate insulin to insure combustion will be a valuable aid in the therapeutic program.

(Concluded from page 2183)

LIPOMAS

Lipomas are in a way analogous to steatopygous deposits except that they are not constant in their distribution. Although not racial they may at least be familial. Blaschko⁴³ has reported a family in which all the males of two generations exhibited multiple subcutaneous lipomas, the growths appearing first at puberty; none of the females of this family had lipomas. Unfortunately he gives no further details. Ewing quotes Murchison, who reported a family in which a father and three daughters exhibited multiple subcutaneous lipomas while nine sons were free of this condition. Other examples of familial lipomas have been reported by Meerbeck, Petre, Leven⁴⁴ and others.

Those who have been so fortunate as to secure specimens exhibiting early stages of lipoma formation (Borst, Bender) have found evidence that the lipoma arises like normal fatty tissue from a preadipose tissue derived from embryonic mesenchymal tissue. Even the so-called heteroplastic lipomas, arising in places where adipose tissue does not ordinarily exist (e. g. the meninges, kidney, periosteum), are believed by Chiari to arise from embryonic misplacement of true adipose tissue or preadipose tissue. Mallory⁴⁵ has described a subcutaneous lipoma with the cells exhibiting the moruloid structure of glandular adipose tissue occurring in an adult. This tumor resembled the glandular adipose tissue of emaciated infants in being reddish yellow and very vascular. Some early liposarcomas so closely resemble reticulo-endothelial tumors as to indicate the common origin of adipose and lymphatic tissues.

Lipomas exhibit a number of interesting features, often being something more than merely circumscribed overgrowths of adipose tissue. Because of the insulating quality of fat, the skin over a lipoma is distinctly cooler than in the corresponding area of the other side of the body, which is a point that may have some diagnostic value. They may appear as symmetrical growths and hence present a problem as to etiology. In some such cases a particularly close connection to nerves may be demonstrated (Chiari) and the tumors may be tender or painful,⁴⁶ but what the relation of the ner-

vous tissue to the etiology of the growths may be cannot now be stated. Such a condition recalls the "adiposis dolorosa" of Dercum. Cases have been described of multiple symmetrical lipomas appearing after a spinal injury which strongly support the idea that the nerves are in some way responsible, perhaps through trophic influence. They occur mostly after the age of 40 and most often in females (73 per cent of 134 patients in one series⁴⁷ were females). Adair, Pack and Farrior⁴⁸ say that when they are multiple lipomas are usually neurolipomas. They observed one instance in a 5 months infant, and Jacobi⁴⁹ said that in the literature he had found "less than thirty cases of congenital lipomas" up to 1884.

Even benign lipomas may contain immature cells, arousing suspicion of a beginning malignant growth, which is explained by the fact that mature fat cells seem to be unable to proliferate, and growth is accomplished by immature cells.⁴⁹ Occasionally lipomas do take on a malignant character, and then they demonstrate nicely the embryonic origin of fat in relation to the primitive myxomatous connective tissue of the early fetus, for such malignant growths are composed of a mixture of adipose and myxomatous tissue, descriptively called liposarcoma myxomatodes, or lipomyxosarcoma. Such tumors may reach great size, especially in the retroperitoneal region. I have observed one that weighed 69 pounds (31 Kg.)⁵⁰ Martin⁵¹ has reported a benign subcutaneous lipoma with teratomatous areas which in fifty-eight years grew to a weight of 59 pounds (27 Kg.).

Ewing⁵² recognizes two types of liposarcoma: (1) an adult fat cell type composed of granular cells resembling those found in chronic inflammation of fat tissue, which may be their starting point; (2) embryonal liposarcoma or lipomyxosarcoma, which exhibits a proliferation of minute vessels, the adventitial or endothelial cells of which, instead of producing fat, form chiefly mucus and occasionally embryonal fat tissue. "The cells, steatoblasts and lipoblasts, are derived from the adventitial layers of the blood vessels. They first appear as granular nucleated cells lying in the rich capillary network and producing a structure which resembles liver tissue. . . . Mucous tissue often appears in the fat anlage." An orange colored lipoma suggests origin from brown fat. Gricoureff⁵³ says that in the embryonic lipoma the myxomatous feature is provided by the stroma rather than the tumor cells, which accords with my own observations.

A particularly interesting feature of lipomas is their relation to the normal storehouses of fat, for there is a widespread belief that the fat in the lipomas is not available to the host as a source of nourishment. This is based on certain reputed instances in which the bearer of a lipoma is said to have become greatly emaciated from some intercurrent disease, notwithstanding which the lipoma either has remained its original size or has continued to grow. Despite the currency of this belief, it is difficult to find specific evidence as to its validity.

46. Emil Ries (Am. J. Obst. & Gynec. 34: 490 [Sept.] 1937) has reported finding painful episacro-iliac lipomas as a common cause of backache, no less than 317 of 1,000 persons examined showing lipomas in this location.

According to Shattock, this belief depends largely on the teaching of Paget, based on a specimen in the museum of St. George's Hospital, with lipomas in the mesentery of a patient with phthisis from whom nearly all the natural fat had been removed; and on a case reported by Schuh of a man with masses of fat in the head, throat and chest, although the abdomen and legs were very thin. Shattock reexamined the St. George specimens, preserved since 1843, and found that some of the masses were lipomas but that some were caseous lymph nodes.

Many years ago (1912) I⁵⁴ investigated this question and found that, as far as the literature was concerned, the evidence was conflicting. Several general statements and but few specific case reports could be found. Of these, some agreed with Paget's idea, others described decrease in size of lipomas during emaciation. The possibility that lipomas might behave in either way is offered by analogy with other localized collections of adipose tissue. Thus, the fat of the camel's hump and of the steatopygous decorations of the Hottentot are drawn on for nourishment when needed, but the sucking pad of the infant's cheek usually retains its fat even in extreme emaciation. Malignant fatty tumors offer an undoubted case of accumulation of fat in spite of most severe depletion of fat from the normal fat depots, for nearly all the cases reported in the literature exhibited marked emaciation.⁵⁵

In my own case of liposarcoma referred to previously, which presented the largest solid tumor of which I can find certain record, the patient was emaciated to the maximum degree. Although there were several pounds of fat and protein in the tumor that might have been used for nourishment, it evidently was not available to the wasting organism, for not only was the subcutaneous fat lacking but even the more resistant perirenal adipose tissue had become almost completely depleted of its fat stores.

But in respect to benign lipomas the matter is not so clear, for well studied case reports of the influence of general nutrition on the weight and dimensions of these growths are lacking. The massive accumulations of fat sometimes seen in the neck and called "Madelung's neck," are said by Madelung⁵⁶ to remain unchanged during emaciation, but these are perhaps not true lipomas. I have recently seen a small (1.5 cm.) lipoma with fat-distended cells standing out in the extremely defatted omentum (fig. 5) of an old man dying of gastric cancer, his weight being but 90 pounds (41 Kg.). In progressive lipodystrophy it has been observed that a lipoma present in the subcutaneous tissues in the area that became depleted of fat remained distended with fat.⁵⁷

Why the wasting body cannot utilize these pathologic fatty masses is an unsolved problem. The few chemical studies of lipoma fat show no differences recognizable by present methods between the fat of lipomas and normal subcutaneous tissues. d'Argenio⁵⁸ says that lipomas contain myelins, which are absent in subcutaneous fat tissue. If so, this serves to rank lipomas with multilocular adipose tissue, which may explain its failure to resorb as readily as depot fat tissue.

It must be admitted not only that malignant tumor cells can build up their own cellular structure of proteins, which are inaccessible to the rest of the wasting body, but can also lay on and withhold fat, which seems in all respects to resemble the normal stored food needed by the emaciated patient. Since normal tissues do not ordinarily store fat for their own use but for the use of the entire organism, this holding of fat by tumor cells when the rest of the body needs it is entirely out of harmony with normal fat metabolism and challenges explanation. Certainly no anatomic peculiarity is known to explain the unavailability of lipomatous fat; there is plenty of blood supply to bring in the fat, so why cannot it be drawn out again? I have tried to see whether there is any difference between the enzymes of lipomas and normal adipose tissue,⁵⁴ but, as far as the

Fig. 5.—Lipoma of omentum (above) retaining its fat during extreme emaciation which has depleted the omental fat tissue (below). The man died of carcinoma of the stomach; he weighed 90 pounds (41 Kg.). Slightly reduced from a photomicrograph with a magnification of 145 diameters.

available means disclosed, lipoma tissue exhibits much the same lipase activity as adipose tissue, and lipoma fat was hydrolyzed by pancreatic juice as readily as fat from normal human adipose tissue.

The apparently anomalous behavior of fat deposits in lipomas suggests that the laying on and giving up of fat in adipose tissue does not depend on a simple reversible reaction, either chemical or physical. It would seem that these processes must be independent of each other and therefore each the result of a special activity of the fat cells. Perhaps in some tumors the cells differentiate only enough to accomplish the storage function, whereas in other tumors both functions are possible, and these lipomas are the ones that are seen to waste away during emaciation. Other tumors derived from the same cells may fail in large measure to acquire

55. Some patients with advanced cancer retain a high degree of adiposity. This paradox has been attributed in some cases to metastasis in the hypophysis, but this explanation does not generally hold, and Mathias (Verhandl. d. deutsch. path. Gesellsch. 26: 289, 1931) believes that anemia from hemorrhage or bone marrow metastases is responsible for adiposity in some cases.

even the storage capacity and appear as the embryonal type of lipomas, which may resemble reticulum cell tumors.

DIFFUSE SYMMETRICAL LIPOMATOSIS

Besides the occurrence of well circumscribed lipomas in symmetrical locations, and with evident or apparent relation to nerve trunks, there is a group of most interesting conditions characterized by symmetrical excess of adipose tissue in diffuse form. This includes the "fat neck" of Madelung and many of the cases of "adiposis dolorosa" or Dercum's disease. Here too there is a relation to the nervous tissues as shown by the tenderness of the diffuse fat deposits, so that the relation to the circumscribed symmetrical lipomas is a close one. Indeed, within the diffuse fatty deposits of symmetrical adiposity there may also occur circumscribed areas resembling simple lipomas. These conditions have been well described and analyzed as understood in 1910 by Lyon.⁵⁹

Fat neck was described by Brodie in 1846, and many cases had been described in England and elsewhere when Madelung published his paper in 1888 in Germany. Therefore it is called Madelung's neck. The disease is characterized by symmetry, diffuseness and special localization of the fatty tumors, but the symmetrical tumors may not arise at the same time. Usually there are fatty deposits in other parts of the body besides the neck, which may appear later or earlier than the others. After removal the tumors do not recur, although new formations may occur about the periphery. It occurs chiefly in men, especially often in alcoholic addicts. Usually these subjects are in good health but occasionally they exhibit such constitutional symptoms as neuritis, arthritis or vasomotor disturbances. It is said that the fatty masses do not disappear spontaneously or vary with changes in the general state of nutrition. Lyon says that the constitutional symptoms of general adiposity, nodular lipomatosis and diffuse symmetrical lipomatosis are essentially the same. Frequently the types blend in such a manner that they cannot be distinguished from one another.

A relation to the ductless glands is shown by all these conditions; in some there is genital hypoplasia, in others changes in the thyroid or pituitary. Thyroid feeding is sometimes of benefit. The fatty tissue shows no characteristic histologic features and seems to be derived from ordinary adipose tissue and not from the special lobulated fat tissues.

Adiposis dolorosa was the appropriate name proposed by Dercum in 1892 for a group of these cases of generalized adiposity in which pain in the fat deposits is an outstanding feature. But, as already indicated, there is no sharp line between adiposis dolorosa and general obesity on the one hand and diffuse symmetrical lipomatosis on the other, for in both these conditions there is more or less tenderness, commonly manifested in the fatty deposits. In typical adiposis dolorosa, asthenia is usually present, often profound, and psychic abnormalities are often manifested. The chemical composition does not differ recognizably from that of normal adipose tissue.⁶⁰

There is nothing constant about the fat deposits, which may be diffuse, nodular or both, symmetrical or irregular, slight or very extensive. Usually the hands, feet and face escape. Likewise the degree and character

of the neuritic and psychic disturbances are extremely varied. Vasomotor instability, anhidrosis or hyperhidrosis testify to the sympathetic disturbances. Many trophic changes, including loss of hair, pigmentation and cutaneous ulcers, have been described.

Although a neuropathic family history is common, familial occurrence and hereditary influences are said not to be common, but Lyon believes that this is often overlooked. Reversing the relation in symmetrical lipomatosis of the neck, females greatly outnumber the males. Often it follows the climacteric. Although thyroid treatment sometimes improves the condition, it rarely if ever cures.

The fat deposits may contain separate embedded lipomas but in general exhibit no specific characters. An interstitial neuritis in the fat deposits is commonly described in the cases examined. Although the thyroid is seldom altogether normal, the changes described are so variable as to fail to establish a relation to the disease. Probably the thyroids of an equal number of persons of the same age dying from any chronic disease would show comparable conditions. The pituitary gland has shown more marked changes, sometimes neoplasia, suggesting a relation to hypophysial dystrophies. Up to the present time the etiology is entirely unknown, but the relation to hypophysial, thyroid and genital dystrophies seems to be indicated.

As Lyon says, it would be easy to collect cases ranging from normal through simple obesity to adiposis dolorosa. Many women who are not obese show tender baggy fat deposits on the arms and hips which differ chiefly in degree from diffuse symmetrical lipomatosis and adiposis dolorosa. Any one or more of the cardinal symptoms of the latter may be present in a given case of obesity, and even cases presenting all the symptoms (asthenia, tenderness, psychic symptoms) except obesity are seen. Anders⁶¹ described as "adiposis tuberosa simplex" cases of common obesity presenting tender fatty lumps in the adipose tissue. Furthermore, as mentioned before, cases of multiple nodular lipomas occur which exhibit tenderness without obesity and with or without other constitutional disturbances. Lyon finds that heredity plays a large role in these various forms of local adiposity and that different types may occur in relatives, indicating the lack of individuality of the types.

Fröhlich's syndrome is another illustration of an adiposity which in some cases verges on the adiposis dolorosa group and on the other side simulates the genital adiposities. I have seen a case that seemed clinically to be typical Fröhlich's syndrome which at autopsy showed congenital syphilis with severe arterial involvement and a structurally normal hypophysis. Also I have examined the body of a man with both testicles destroyed by syphilis who exhibited extreme obesity with a fat distribution recalling these syndromes. This corresponds with the observations of Tandler and Grosz⁶² on the similarity of the changes in hypophysial and testicular hypofunction. In castration obesity, as in simple constitutional obesity, the fat accumulation is said not to be entirely dependent on oversupply of fat, for these persons continue to gain weight on a restricted diet. Umber has described a case of obesity following oophorectomy in which the weight remained constant on a diet supposed to furnish only 900 calories a day. Such statements seem to suggest that the law of conservation of energy has been repealed.

Lipodystrophia progressiva⁶³ is a remarkable and puzzling condition, characterized by loss of fat in the upper part of the body even to the degree of emaciation, while fat remains abundant and usually excessive below the waist line. The title "lipodystrophia cephalothoracica," proposed by Maranon and Alvarez Cascos,⁶⁴ gives a more accurate impression of the nature of the malady, for after a short period of progression the condition remains stationary. However, in a case reported by Bigler⁶⁵ the loss of fat was in the lower extremities, with persistence of the fat in the cephalothoracic region. Overfeeding causes fat to increase in the lower parts of the body but not in the emaciated parts. In one case a lipoma present in the upper part of the body persisted when the subcutaneous fat disappeared.

Like adiposis dolorosa, it occurs chiefly in females (about 2 to 1). In two cases reported with necropsies the fat in the body cavities was normal, as were the endocrine glands. The supposed relation to endocrine disturbances is supported by the fact that some patients with this dystrophy exhibit a redistribution of fat under thyroid feeding, the dimension of the hips decreasing while the axillary circumference increases (Beck); but others have not confirmed this. The general health is good, as are the sex functions. It is probable that minor degrees are common, and even frank cases are probably not so rare as the literature suggests, for Parmelee⁶⁶ was able to report six cases.

The hormone factor in these cases is, however, hard to reconcile with the topographic limitation, as it is in cases in which the adiposity is unilateral, but it must be recalled that unilateral acromegaly has been described. Trophic nerve changes are often present, which serves to relate this condition with adiposis dolorosa and the rest of the lipodystrophies. Microscopic study shows merely a loss of fat tissue from the subcutaneous tissue of the dystrophic part of the body without persistence of the embryonal type of defatted adipose tissue cells as occurs in ordinary emaciation, at least in the case (Bigler's) I have examined. This disappearance of fat cells explains the inability of the affected subcutaneous tissues to store fat, no matter how much is assimilated.

Maranon and Alvarez Cascos, who say that this condition is especially common in Spanish women, suggest that it is merely an individual exaggeration of a tendency for an irregular distribution of subcutaneous fat often seen in less degree in women, dependent on chromosomal constitution and perhaps augmented by endocrine abnormalities, especially hypothyroidism, which is present in 20 per cent of the cases. As pointed out by Lauter and Terhedebrügge,⁶⁷ in thyroidogenous emaciation the buttocks retain relatively more fat while the thorax loses relatively more. No consistent changes have been found in the endocrine organs.

GENERAL OBESITY

The topic general obesity covers so much ground that it is not feasible to discuss it within the space of this paper, nor is it really a disease of fat tissue but of general metabolism, so I shall refer to only one phase of its experimental study, which, having been presented outside the medical literature, has been overlooked in

most discussions of obesity. This is the experimental demonstration of the significance of heredity for the occurrence of adiposity, and important possibilities opened for future studies on obesity, by the observations of Danforth⁶⁸ of Stanford University on hereditary obesity in mice. In a strain of yellow mice there occurs a pronounced form of adiposity, more marked in females, which is associated in cross breeding experiments with the yellow color. These animals lay on much more fat than control mice on the same diet, and this fat can be utilized when required by fasting. That human obesity is in large measure determined by heredity has been shown by numerous clinical studies, among the more recent of which may be mentioned the report of Gurney.⁶⁹

PATHOLOGY OF ADIPOSE TISSUE

Beyond the various types of overgrowth previously discussed, little has ever been said or written about diseases of this widespread and quantitatively important tissue. That it may play any part in systemic disease seems never to be considered. But when one observes the character of the fat cells when they are free from fat and notes their abundant cytoplasm and the gland-like vascularization of adipose tissue, the possibility presents itself strongly that such a tissue may play a part in general metabolism which has been overlooked, until recent studies, cited previously, have shown its function of converting carbohydrate into fat. The presence of great deposits of fat in the cells need not prevent their exhibiting active metabolism, since the cytoplasm is outside the fat and in close relation to the blood supply. As stated previously, I have found that the production of maximum degrees of fatty deposition in liver cells does not appreciably decrease their capacity to oxidize uric acid. The work of Wassermann, indicating that adipose tissue is part of the reticulo-endothelial system, suggests that it may play a part in immunity. The demonstrated role in fat formation indicates functional activity not formerly suspected and supports the suspicion that other unrevealed activities may also be going on in this neglected tissue.

When extensive fatty changes are produced in the liver and other parenchymatous organs by phosphorus, arsenic and other steatogenic poisons, the fat, at least in part, comes from the adipose tissue depots, for extreme emaciation may interfere with the production of this fatty metamorphosis.⁷⁰ Balan⁷¹ says that in phosphorus poisoning the adipose tissue fat becomes so altered that it stains with Nile blue, indicating a change in the state of the stored fat, presumably related to its transportation.

NECROSIS OF ADIPOSE TISSUE

Only a few disease processes have been recognized as affecting adipose tissue itself. Perhaps most discussed is the focal necrosis of the fat tissue that occurs when adipose tissue comes in contact with pancreatic juice. Here the cleavage of the fat by the lipase is followed by soap formation, giving rise to the characteristic circumscribed opaque white areas in the adipose tissue. By using lipase from vegetable sources and artificial lipases, as well as pancreatic enzymes, Neal and Ellis⁷² have shown that lipase rather than trypsin

is responsible for pancreatic fat necrosis. Pure pancreatic juice will not produce fat necrosis unless activated by intestinal juice,⁷³ and presumably by tissue kinases. Rewbridge⁷⁴ has shown that bile in the peritoneal cavity may produce fat necrosis, apparently through affecting tissue permeability so that the enzymes escape from the pancreas. The products of the fat cleavage seem to have no part in the toxic state that results from the acute pancreatitis or peritonitis which often accompany peritoneal fat necrosis.

A similar condition, at least morphologically, is sometimes seen where fat tissue has been traumatized, even without the possibility of contact with pancreatic juice. It has been described chiefly in the subcutaneous fat tissue of the abdominal wall and the female breasts.⁷⁵ As many of the cases occurring in the female breast present no history of trauma, it is possible that it may sometimes result from escape of duct contents into the adipose tissue,⁷⁶ and in some cases it may be part of a generalized disease of adipose tissue, nonsuppurative panniculitis. It is not infrequently seen in fat cattle killed in the Chicago stock yards and presumably is the result of the traumatism that occur during transportation. Also it may result in infants from birth trauma.⁷⁷

SCLEREMA NEONATORUM

A remarkable pathologic condition of adipose tissue is seen in the condition known as "sclerema neonatorum,"⁷⁸ in which the subcutaneous adipose tissue becomes hard and rigid, like chilled fat. In those cases in which the process is diffuse, the affected infant may feel like the body of a fat sucking pig brought out of the refrigerator. Sometimes the process is localized, and the affected areas may undergo necrosis, even with subsequent calcification, constituting "adiponecrosis subcutanea neonatorum." This condition seems to depend on a deficiency in olein in the subcutaneous tissues, which causes the adipose tissue to have an abnormally high melting point.⁷⁹ The resulting mixture of stearin and palmitin crystallizes at body temperature and the crystals may incite an inflammatory foreign body reaction.⁸⁰ According to Harrison,⁸¹ these crystals have a melting point of from 40 to 50 C., whereas crystals from the fat of normal infants melt at 30 C. Whether the deficiency in triolein responsible for the raised melting point is a developmental defect or a postnatal abnormal utilization of the olein is not known. In infants with such abnormal fat, obstetric trauma is usually the cause of the local necrosis, ordinarily noted only in the subcutaneous tissues, but occasionally in the perirenal fat.⁸² Siwe⁸³ says that when adults exhibit adiponecrosis their fat is found to exhibit the same excessive proportion of palmitin as is seen in affected children and that similar changes may be obtained in animals injected with palmitin and palmitic acid.

LIPOGRANULOMATOSIS

Local necrosis of adipose tissue from whatever cause may stimulate proliferative reactions leading to the formation of what are essentially foreign body tubercles but with special characteristics because of the abundant lipophage cells and often multinucleated foreign body giant cells. At times the fat is set free to form small oil cysts surrounded by a zone of macrophages and giant cells.⁸⁴ In other cases the abundance of proliferating cells has suggested the presence of a neoplasm, and it is probable that dermatologists have looked on these "lipophage granulomas" as tuberculids (e.g. Darier sarcoid or erythema induratum Bazin) according to Abrikossoff.⁸⁵ They may become calcified, but this seems to be unusual. Harbitz⁸⁶ and others report cases in which these "lipogranulomas" were mistaken for malignant tumors and led to excessive operative procedures, especially when they have appeared at the site of the trauma of a previous operation for removal of a tumor. It is not sufficiently appreciated that when fat tissue is injured the liberated fat may act as a foreign body, especially if crystals of fatty acids or soaps are formed, and then the picture of lipogranulomatosis appears with its proliferation of fibroblasts and foreign body giant cells. The histologic changes of sclerema neonatorum are of this character. The fundamental principles of the reaction of tissues to mixtures of human fat, soaps and cholesterol have been studied by Hirsch.⁸⁷

ATROPHY AND HYPERTROPHY

In those parts of the body where adipose tissue has the function of filling in spaces, a condition known as "serous atrophy of fat" is seen when there has been marked emaciation. This is nothing else than a form of "edema ex vacuo." The fat having been absorbed, the space it formerly occupied is filled with serous fluid, mostly as an interstitial edema, although the cytoplasm of the depleted fat cells apparently also participates in the water storage (fig. 3).

The reverse process often occurs when a solid tissue decreases in size and the place it formerly occupied becomes filled with adipose tissue, constituting essentially a compensatory hypertrophy of fat. The bone marrow is probably the tissue exhibiting this change most frequently, since the marrow of the long bones is seen to fluctuate with every large variation in the demand for blood cells, from yellow fatty marrow composed almost solely of adipose tissue to cellular red marrow, and back again to adipose tissue. Likewise, when bone is absorbed its place is often filled by fatty marrow. In adiposity the excessive fat tissue may crowd out the muscle fibers in the heart wall, especially near the apex. Sometimes the process is so extensive that the fat may extend through to the endocardium. In such cases a weakened heart wall may rupture through the fatty portion, and the fat infiltration may be responsible for slow or sudden cardiac failure, even without rupture.⁸⁸ Also the pancreas may have its glandular tissue crowded out by fat tissue, so that little remains but the islets, which seem to be completely spared. Apparently the factor of safety in the pancreas is large, for assimilation of food seems to continue to be excessive in such adipose subjects. When pancreatic

atrophy follows duct obstruction, marked replacement with adipose tissue occurs whether the patient is obese or not.

Replacement adiposity is often seen in those forms of chronic nephritis in which the size of the kidney is reduced, the adipose tissue at the hilus increasing *pari passu*, so that the kidney may appear externally to be of about normal size, despite loss of half or more of its secretory tissue. In pseudohypertrophic muscular atrophy a similar compensatory hypertrophy occurs, the muscles appearing as large as or even larger than normal through replacement of the lost muscle fibers by adipose tissue. Where the adipose tissue comes from in these conditions has not been determined—whether it is new formation from undifferentiated cells, acquisition by fibroblasts of the power to lay on fat or merely an increase in the fat content of the existing local adipose tissues. It is suggested by Wassermann that in the fatty replacement of atrophic muscles, the remaining capillary bed transforms itself with the intramuscular connective tissue into a new adipose tissue.

INSULIN LIPODYSTROPHY

The common use of insulin has produced a pathologic state in adipose tissue which may occur under other conditions but which has hitherto been unrecognized. This is a localized melting away of the fat in the vicinity of the sites of injection, sometimes in areas as large as the palm of the hand, where the panniculus adiposus is entirely absent and the thinned, fatless cutis lies directly on the underlying muscular and fascial structures. The process develops without evidence of inflammation, and as yet no satisfactory explanation has been advanced. Insulin preparations do not contain lipase that might hydrolyze the fat. Nichols⁸⁹ suggests that the concentration of insulin causes an active local combustion of carbohydrate, which in turn causes active combustion of the fat. Sometimes areas of hyperplasia of adipose tissue may appear side by side with the atrophic areas;⁹⁰ in fact, Priesel and Frey⁹¹ state that local adipose hypertrophy occurs more often than local atrophy.

PANNICULITIS

Under the title "Relapsing Febrile Nodular Nonsuppurative Panniculitis," Christian⁹² has described a disease of unknown etiology characterized by recurring attacks of fever, associated with a peculiar generalized nodular inflammation of the subcutaneous tissue, leading in time to areas of atrophy. This condition had been previously described by several others under various titles. Binkley⁹³ says that of thirteen cases reported in the literature eleven were in females and two in males. The process histologically resembles that seen in various forms of necrosis of fat tissue with inflammatory reaction, such as is seen in traumatic fat necrosis of the breast. Occasionally liquefaction of the fat takes place as in the case reported by Shaffer,⁹⁴ the resulting oil discharging externally from the lesions.

SUMMARY

There is now conclusive evidence that adipose tissue is not merely a connective tissue which stores fat but

a special organ which has other functions. Therefore it may play a part in disease processes not yet recognized.

Until more is known about the extent and variety of these functions it cannot be known just how much adipose tissue modifies or is modified by various disease processes. But since many of the physiologic functions of tissues have been revealed by their pathologic deviations, the pathologists as well as the physiologists should give more consideration to the possibility of there being hitherto unappreciated activities and maladies of the adipose tissues, which are to be considered as constituting, like the widely distributed bone marrow, one of the largest of the organs of the body. Adipose tissue is not merely a storehouse; it is also a manufacturing plant in active operation, not only producing some or all of its own stored materials but probably conducting other processes not yet revealed to the incurious passers by.

ACUTE INVERSION OF THE PUERPERAL UTERUS

A RECORD OF TWENTY-ONE CASES

W. BENSON HARER, M.D.

AND

JOHN A. SHARKEY, M.D.

PHILADELPHIA

Acute inversion of the puerperal uterus, the turning inside out of the uterus, is one of the rarest of obstetric complications. When only a portion of the fundus uteri is inverted, one speaks of the condition as a partial inversion. When the entire organ is inverted, it is called a complete inversion. In the strict sense of the word the latter condition is rare, because there is usually a rim of cervix which does not turn inside out and hence most cases should be classed as partial inversions. From the practical standpoint, however, when the fundus uteri protrudes completely through the cervix the condition is called a complete inversion of the uterus. Such an organ may be lying entirely within the vagina or the inversion may be accompanied by prolapse, in which event the inverted uterus protrudes from the vulvar orifice as a large, soft, bleeding mass of tissue closely resembling a large pedunculated fibromyoma.

Statistics vary widely as to the incidence of this condition. Beckmann¹ states that acute inversion of the puerperal uterus was not encountered in more than 250,000 deliveries at the St. Petersburg Lying-in Hospital. Irving reports an incidence of inversion of the uterus of one in 7,837 cases at the Boston Lying-in Hospital. The cases included in this report consist of fifteen cases of acute inversion of the puerperal uterus occurring in Philadelphia during the years 1931-1938 inclusive, five cases occurring in one hospital outside of Philadelphia during the years 1933-1938 inclusive and one case occurring in Philadelphia prior to 1931. If one considers the frequency of this condition from the standpoint of the five cases occurring in one hospital outside of Philadelphia in a total of 3,700 deliveries, this would give an incidence of one inversion in 740 deliveries. Obviously this is much greater than the incidence of inversion generally encountered throughout the world and is an indication of the fallacy of statistics based on the experience of a single hospital

or a small group of physicians. During the eight year period 1931-1938 inclusive there were 243,602 deliveries reported to the registrar of vital statistics in Philadelphia. A brief questionnaire concerning inversion of the uterus was sent to every institution in Philadelphia in which any obstetric patients were treated during this period. We are glad to be able to report that every institution so approached replied to us and we were given free access to the records of all cases of acute inversion of the uterus. Because of the serious nature of this obstetric complication we believe that we may safely assume that all patients with inversion of the uterus occurring in delivery in the home would eventually be sent to a hospital. We therefore believe that we have studied all cases of inversion of the uterus occurring in Philadelphia, a city of more than 2,000,000 people, and in the practices of more than 3,000 physicians during a period of eight years. Fifteen cases in all were so collected. This gives an incidence of one case of acute inversion of the puerperal uterus in 16,240 deliveries. Of our total of twenty-one cases, fourteen occurred in primiparas and seven in multiparas.

Inversion of the uterus may occur spontaneously but is usually due to improper conduct of the third stage of

"dimple" which predisposes to inversion of the uterus. In other cases there appears to be some abnormality in the innervation of the uterus which results in abnormal contraction of the uterine muscle fibers and the production of "inert" areas or areas of softening in the uterine wall. A personal case of one of us (W. B. H.) in 1936 illustrated this strikingly:

Mrs. C. K., a primipara aged 29, went into labor spontaneously at term. There was marked inertia uteri and it was noticed that the entire left half of the uterus remained soft and flabby during the labor pains. Finally, after thirty hours of such labor without much progress, cesarean section was performed. The uterus was grossly normal, but following the extraction of the fetus only the right half of the uterus contracted and retracted, the left half remaining large and exceedingly flabby. This produced a marked asymmetry of the uterus and actually brought about a dimpling of the fundus exactly like a partial inversion of the uterus. To overcome this obvious tendency to inversion and as a prophylaxis against postpartum hemorrhage, the interior of the uterus was packed with gauze before closure of the uterine incision.

As pointed out by Watson,² the law of reciprocal innervation of organs controlled by a sphincter muscle applies to the uterus. In such an organ the innervation is such that there is contraction of the longitudinal muscle fibers and simultaneous relaxation of the circular (sphincter) fibers to bring about emptying of the organ; in the case of the uterus such action, when excessive, may readily produce a spontaneous inversion.

All these causes of inversion of the uterus are illustrated in our twenty-one cases, as shown in table 1. It is readily apparent from this table that sixteen, or 76 per cent, of these twenty-one cases were due to errors in technic and were therefore theoretically avoidable.

The time of occurrence of the inversion with respect to the third stage of labor is of considerable interest and is shown in table 2. In one case the inversion recurred three hours after the manual replacement of the first inversion.

Table 2 shows that 57 per cent of the cases in this series occurred before the placenta was separated from the uterine wall. In an additional 28.5 per cent inversion followed immediately on the expulsion of the placenta and was caused by efforts on the part of the attending physician to express the placenta. Only three cases (14 per cent) occurred one half hour or more after the delivery of the placenta. All three were cases of spontaneous inversion.

The prognosis in acute inversion of the uterus is very bad. Cooke states that there is a mortality of about 40 per cent. In our series of cases there were nine deaths and twelve recoveries, a mortality rate of 43 per cent.

The important signs and symptoms of acute inversion of the puerperal uterus are hemorrhage, shock and the absence of the rounded uterine fundus on abdominal palpation. The hemorrhage may be only moderate in amount but is usually quite profuse, the patient rapidly becoming exsanguinated. When the placenta remains attached to the inverted uterus the amount of bleeding is usually moderate. When the placenta has been detached from the uterine wall either before or after the inversion occurs there is interference with the normal retraction of the uterus and so failure of constriction of the vascular sinuses in the placental area, with consequent serious hemorrhage. In our series hemorrhage was very profuse in twelve, moderately

labor. The most frequent cause of inversion of the uterus is suprafundal pressure applied to a relaxed uterus in an effort to expel the placenta. Traction on the umbilical cord before complete separation of the placenta and with the uterus relaxed is also a frequent cause of inversion. Attempts at manual removal of an adherent placenta may bring about an inversion of the uterus in either of two ways: First, the placenta may not be completely detached before the hand is withdrawn from the uterus and the traction on the adherent placenta may initiate the inversion, or, second, the hand and forearm may create a piston-like suction which inverts the uterus. A short umbilical cord or one relatively shortened by being looped about the fetal body may cause traction on the attached placenta and so produce inversion of the uterus immediately following the birth of the child. Various explanations for the spontaneous occurrence of inversion of the uterus have been advanced. Increased intra-abdominal pressure brought about by coughing, sneezing, vomiting or attempts to sit up may produce inversion of the uterus. The theory has been advanced that there is an abnormal distribution of the muscle fibers of the fundal portion of the uterus with a preponderance of circular fibers over the longitudinal ones in some of these cases. It is stated that in those cases in which the placenta is attached to the fundus uteri there is a thinning of this portion of the wall of the uterus and a softening due to the increased vascularity which results in imperfect contraction of the muscle fibers and the production of a

2. Watson, B. P.: Personal communication to the authors.

severe in six and only slight in three cases. Shock is almost invariably present in inversion of the uterus and, even when the hemorrhage is very profuse, is out of all proportion to the amount of blood lost. No other obstetric condition is accompanied by such acute and profound shock. The skin becomes cold and clammy; the pulse becomes extremely rapid and so weak as to be imperceptible at the wrist. Within a few minutes after an acute inversion of the uterus a previously normal woman is in an extremely precarious condition. In this group of cases the pulse rate averaged 160 per minute and serious shock was present in twenty cases. One showed no evidence of shock—a most unusual condition in inversion of the uterus.

The differential diagnosis of acute inversion of the uterus is not difficult. Most commonly it is mistaken for a pedunculated submucous fibroid, as was the situation in two of the cases in this series. The absence of the firm rounded mass of the uterus above the symphysis pubis and the presence of hemorrhage and shock should immediately suggest the possibility of an acute inversion of the uterus and the institution of the proper treatment for this condition.

Since more than 75 per cent of all cases of inversion of the uterus are preventable, prophylactic treatment of this condition is of prime importance. The preventive treatment of this rare but serious complication of pregnancy must be started in our medical schools. Medical students must be more adequately instructed in the physiology of the third stage of labor, particularly with respect to the mechanism of the separation and expulsion of the placenta. They must be impressed with the importance of waiting until the placenta has separated before efforts are made to expel it and must be made to understand the danger attendant on pulling on the umbilical cord or on attempting the Credé method of expressing the placenta in the absence of spontaneous, firm uterine contraction. When these fundamentals of obstetric practice become deeply instilled in all physicians and there is consequent improvement in the conduct of the third stage of labor, then indeed will acute inversion of the puerperal uterus become a rare condition.

Such training will require time and is a project for the future. In the meantime one is occasionally faced with the necessity of promptly and properly handling this condition. When, as in the experience of one of us (W. B. H.), this complication occurs in each of two successive deliveries or when, as in the experience of the other of us (J. A. S.), one is called in consultation on five such cases in a relatively short time, this condition assumes colossal proportions and becomes a never to be forgotten catastrophe, and the matter of proper treatment becomes of paramount importance.

At the present time there is considerable divergence of opinion as to the proper treatment of acute inversion of the uterus; Williams,³ Beck,⁴ Titus⁵ and Cooke⁶ advise immediate replacement of the inverted uterus. Zangemeister⁷ reported a 23 per cent mortality in this condition when operation was undertaken in the pres-

ence of shock and no mortality when operation was deferred until after reaction had taken place. De Lee⁸ originally advocated immediate replacement only to control severe hemorrhage, but in an editorial comment in the Year Book of Obstetrics and Gynecology for 1938 he modified his stand and now advises immediate replacement when it can be readily accomplished. Irving and Kellogg⁹ are very emphatic in their belief in deferring replacement of the inverted uterus until after recovery from the shock.

Such divergence of opinions can be explained only on the basis of the personal experiences of these men and the particular type of case that they encountered. Even after many years of active service covering thousands of obstetric cases one sees only few cases of inversion of the uterus. The late Prof. B. C. Hirst saw only eight such cases. We have each had personal experience with five cases of inversion of the uterus, a total of ten different cases, and therefore feel entitled to express our own opinions as to treatment.

We believe that the inverted uterus should be replaced immediately by gentle taxis when the patient is seen shortly after the inversion has occurred. Active anti-shock treatment should at the same time be started by an assistant and continued until the patient has reacted

well. In our cases we have accomplished replacement without much difficulty and, we believe, without adding appreciably to the shock already present. If there is a tendency toward constriction of the cervix, this may be overcome and the replacement of the uterus facilitated by the intramuscular injection of from 0.5 to 1 cc. of solution of epinephrine hydrochloride (1:1,000) as advocated by Urner.¹⁰ In our cases and in those of this series so treated by other physicians the results of immediate manual replacement of the uterus have been very satisfactory. In all these cases improvement was noted immediately after the uterus was replaced. In a total of thirteen cases of immediate replacement of the inverted uterus there were eleven recoveries and two deaths. One death occurred in a case in which inversion complicated eclampsia. The other death occurred as a result of recurrence of the inversion three hours after its first replacement. In this case the attending physician did not arrive at the hospital until more than an hour after the recurrence of the inversion and it was then found to be impossible to replace the uterus.

Under modern conditions of hospital obstetrics practically all patients are surgically prepared and anesthetized at the time of actual delivery. Since most cases of inversion of the uterus occur during or immediately

after the third stage of labor, these patients are under perfect conditions for the immediate replacement of the uterus. Many will not even require additional anesthesia. A change of gloves is probably all that is needed on the part of the attending physician. The inverted uterus is usually quite soft and relaxed at this time, so that replacement can be effected easily and quickly. The whole procedure can be accomplished before serious shock develops or much blood is lost. It must be emphasized that replacement must be effected immediately to insure good results.

If the attending physician is not competent to replace an inverted uterus and a consultant must be called, considerable time may elapse before his arrival. In such cases he is likely to find the patient in profound shock and greatly exsanguinated. On examination of such a patient the cervix is found to be so constricted as to make replacement of the uterus extremely difficult or impossible. Obviously such a patient is an extremely

tion or by the better known Spinelli¹² modification. In this operation the constricting ring of cervix is incised in the midline anteriorly. The uterus is reinverted and the uterine incision then repaired as in an anterior vaginal hysterotomy. Huntington advocates the abdominal approach for reinversion of the uterus. In his method the abdomen is opened by a midline incision below the umbilicus. The uterus is then replaced by grasping the invaginated portion with strong vulsellum forceps on opposite sides of the rim and pulling it up in a hand over hand fashion. After complete replacement of the uterus it is packed vaginally.

Two of these patients were treated by operative means. In one case a laparotomy under ethylene anesthesia was done five hours after inversion and the uterus replaced by the method of Huntington. The patient died two hours later. In the other case the condition was diagnosed as a pedunculated fibroid and a laparotomy was done for hysterectomy. When the peritoneal cavity was opened it was found that the uterus, which had actually been inverted, had been replaced in the process of packing the vagina prior to operation. Hysterectomy was done and on examination of the excised uterus no fibroid was found. This patient recovered.

The effect of inversion of the uterus on subsequent pregnancy and labor is interesting. Not many such cases have been reported. In several such cases, as for example the one reported by Fox,¹³ the uterus inverted again at the time of a subsequent delivery. In other cases subsequent delivery has been uneventful. Cesarean section is indicated in subsequent pregnancies in those cases in which inversion was treated by a surgical procedure such as Küstner's, Spinelli's or Haultain's operation. One of the patients in this series has been delivered recently without any abnormality.

CONCLUSIONS

Seventy-six per cent of the cases in this series were due to errors in technic and therefore were theoretically avoidable.

Immediate manual replacement of the inverted uterus together with active anti-shock treatment gave the best results. Intermediate and delayed manual replacement and surgical replacement results in a high mortality.

The Span of Life Has Not Been Lengthened.—In the common way of thinking longevity really means living past 80 years, and great human longevity means being a nonagenarian or centenarian. Progress in medicine and improvement in the public health have done little or nothing about enabling the individual to achieve such a goal, as the cold statistical facts about the order of human dying make abundantly clear. The span of human life has not been lengthened, and there is no present prospect that it soon will be. The average duration of life is all that has been altered, and that has been accomplished chiefly by giving more babies a fairer start in life's journey than they use to have. Because more of them get by the early and very difficult hurdles, absolutely more of them survive at later ages. But the terms of the bet that any individual man aged 70 today can safely lay that he will be alive at 90 appear to be not quite as good as they were fifty years ago.—Pearl, Raymond: The Search for Longevity, in Landmarks of Medicine, New York, D. Appleton-Century Company, 1939.

poor risk for any operative procedure and so one's efforts should be directed toward the control of bleeding and the combating of shock. The hemorrhage may be minimized by pushing the inverted uterus up into the vagina and packing around it with sterile gauze. Intravenous dextrose or acacia followed as soon as possible by blood transfusion, the application of external heat and the administration of morphine sulfate and cardiac stimulants may be sufficient to overcome the shock. The situation, however, is always desperate. In one of the cases in this series in which no attempt was made to replace the inverted uterus but in which all other treatment, including blood transfusion, was used, the patient died in three hours. In another case after moderate but unsuccessful effort at replacement of the inverted uterus death occurred within two and three-quarters hours. These patients were all in deep shock and markedly exsanguinated. In three cases of intermediate replacement the uteri were replaced with great difficulty and all three patients died. In another case the uterus was replaced manually after an interval of eleven hours during which time active anti-shock treatment was carried out. In this case death occurred six hours after replacement of the uterus. Kellogg speaks of cases of inversion of the uterus in which constriction of the cervix has occurred as a subacute inversion. In many such cases, and in all cases of chronic inversion of the uterus, manual replacement is impossible. In such cases treatment must be effected by surgical means. Replacement of the uterus in these cases may be effected vaginally by Küstner's¹¹ opera-

EXPERIMENTAL HIBERNATION OF
METASTATIC GROWTHS

PRELIMINARY REPORT

ARKELL M. VAUGHN, M.D.

Associate Clinical Professor of Surgery, Loyola University
School of Medicine

CHICAGO

In recent months there has been considerable publicity concerning hibernation or "freezing" in cancer cases. To ascertain the practicability of the method I undertook observations on six cases of hopeless metastatic cancer after visiting the clinic of Dr. Fay and Dr. Smith in Philadelphia and noting the methods they employed in their original observations on the effects of cold in cases of human cancer. In these six cases every known type of treatment had been given without results. It was my aim to observe whether or not hibernation would retard the cancerous process or alleviate the pain.

Fay¹ in 1936 first made repeated microscopic studies on the effect of reduced local temperatures on carcinomatous growths, and to him due credit must be given. He presented clinical, pathologic and biologic evidence that temperature plays one of the most important roles in the activation of embryonic cell growth.

In this article, hibernation as defined by Smith and Fay means a general reduction of body temperature below the critical level of 95 F., and refrigeration means the local application of cold by means of ice water circulated through a specially constructed apparatus designed to fit the structures of the cooling process.

Fig. 1 (case 1).—Temperature, pulse and respirations during forty-three and one half hours of hibernation. Note the increase in pulse rate as the temperature returns to normal. Also the slight variations in the respiration.

The sequence of events leading up to this research is as follows:

1. Fay¹ studied the body surface temperature of various parts of the body, based on a neurologic dermatome plan. He noted that temperatures in

the extremities might fall from 12 to 22 degrees below the normal for the mouth, while the temperature of the breast, lying in the fifth thoracic segment, was extremely variable and showed an increase in temperature from 0.5 to 3 degrees above the temperature of segments lying within 2 inches on each side.

2. Malignant and metastatic bone tumors of the hands and feet are extremely rare, as has been shown by Coley and Higinbotham.² Mason³ noted that carcinomas of the hands and feet are equally rare and are of low grade malignancy. Pack and Adair⁴ brought

Fig. 2 (case 2).—Temperature, pulse and respirations during fifty-four and one half hours of hibernation. Note the rectal temperature of 83.2 F., the lowest temperature reached in this series of cases.

out the fact that melanoma is the only form of tumor occurring with any considerable frequency on the hands or feet. Geschickter and Copeland⁵ emphasized the comparative infrequency with which skeletal or bone metastases involve the extremities, while skeletal metastases occur more frequently in the pelvis, upper part of the femur, ribs, spine and skull, where there is a more abundant blood supply with resultant higher temperature than in the extremities.

3. The work of Huggins and Noonan⁶ demonstrated that red bone marrow present in the tail segments and metatarsal bones of newborn rats normally disappeared from the tail and the extremities in approximately two weeks, if the animals were exposed to environmental temperatures. If, however, the distal half of the rat's tail was implanted into the abdomen or back or the feet were amputated and placed in the abdominal cavity, red bone marrow persisted during the long period of observation. The portion of the tail exposed to environmental temperatures, however, showed the replacement of red bone marrow by yellow bone marrow, and it was concluded that the favorable temperature of the body was responsible for the retention of activity of the red bone marrow. This shows that heat or warmth is necessary for normal cell growth and mitosis. Conversely, since carcinoma is thought to be an excessive

or wild growth of cell tissue, cold in the form of hibernation or refrigeration should tend to decrease this growth, diminishing the blood supply to this outflow tissue.

Fig. 3 (case 2).—Appearance of the pelvis and upper parts of the femurs, showing extensive metastases.

4. Smith⁷ has shown that varying the temperatures during incubation and growth periods of chick embryos is invariably followed by some alteration from normal, in retarding development, in producing malformations

Fig. 4 (case 3).—Temperature, pulse and respirations during forty hours of hibernation. The patient reacted unfavorably.

and actual monsters or in disintegrating the embryonic tissue early in its effort to differentiate. There is a narrow range which might be spoken of as the optimal zone in which normal growth, differentiation and

organization of the tissues take place with the development of normal chicks. This range is between 97 and 104 F., although with either the upper or the lower level there will be an appreciable diminution in the number of viable chicks. Above 105 F. the temperature is too great for the successful growth and differentiation of embryonic tissue. At the lower level there is a critical temperature lying at approximately 95 F. at which there will be marked retardation in the development of the embryo and a viable chick will only rarely develop; if the chick does develop, there will be marked deformity.

Fay and Smith point out that regressive cell changes have been noted where local temperatures of from 40 to 50 F. have been employed constantly for from ten to twenty-eight days. Observations on general reduction in body temperature to below 90 F. have been carried out in the hope that deep metastatic lesions might be unfavorably influenced in their growth response to subcritical temperature, if these could be maintained for extended periods of time. In our hibernation we used

Fig. 5 (case 4).—Temperature, pulse and respirations during thirty-one and one half hours of hibernation.

the temperature 95 F. as the upper level, the lowest temperature being 83.2 F. rectally. Fay⁸ reduced the temperature of one patient to 74 F. No one knows as yet how low a temperature may be reduced to be compatible with life in the human being.

A survey of the problem revealed that malignant tumors occur most frequently in areas associated with higher temperatures, such as the uterus, breast and gastrointestinal tract. Likewise the occurrence of metastatic carcinomatous lesions is usually in areas with higher temperatures, as the lungs, liver and brain, as well as the central, better vascularized areas of the skeleton, as the pelvis, upper part of the femur and spine. In other words, carcinoma thrives best in organs which contain an abundant blood supply and are warmer than certain other parts of the body, such as the extremities.

The aim of these experiments, therefore, was to reduce body temperature below the critical level of 95 F., which would produce a vasoconstriction of the blood vessels and cause less blood to flow through the cancerous organ. In this way I hoped to retard the growth of the cancerous lesion, for the time being at

8. Fay, Temple: Personal communication to the author.

least. Up to the present time six hibernations have been performed in six cases. No deaths have occurred during the hibernation. Two of the six patients are alive and fairly comfortable seven and eight months after treatment. Several referred patients were refused hibernation because they were in the terminal stages with only a few hours' life expectancy. All our cases were hopeless. Each patient had received all the known orthodox treatments, such as high voltage roentgen therapy, radium, lead and calcium. A ray of hope was offered to them by hibernation, by which they sought to obtain relief.

PROCEDURE

A specially equipped air conditioned room was provided at Mercy Hospital in which a room temperature of 60 F. was maintained as closely as possible. Several

patients do not remember the shivering stage, although they may complain at the time of feeling cold. A considerable amount of paraldehyde was given throughout the entire course of treatment in the earlier cases

Fig. 6 (case 4).—Appearance of pelvis and upper femurs before hibernation, showing metastases (Aug. 21, 1939).

hours before hibernation was started sedation was given by mouth or rectum in the form of pentobarbital sodium, phenobarbital, paraldehyde, bromides or choral hydrate. Avertin with amylene hydrate was given rectally in the first three cases, while intravenous evipal soluble was given in the last three. Paraldehyde was introduced into the stomach through a nasal catheter in order to keep the patient quiet while the temperature was being lowered (Fay-McCravey technic). When the temperature reached 90 F. or less, little or no sedative was given, as the patients lay quietly in this state; they moved occasionally, could be aroused but soon returned to slumber, answered questions in a logical manner and even recognized members of the family. One patient was placed on a bed pan and had a voluntary micturition with the temperature at 86 F. The patients remember nothing from the time the anesthesia is administered until they come out of the hibernation. One patient, on arousing from the hibernation, asked when she was to get the "freezing treatment." The

Fig. 7 (case 4).—Appearance of the pelvis and upper parts of the femurs one month after hibernation. Note pathologic fracture of the right femur (Oct. 10, 1939).

Fig. 8 (case 4).—Appearance of the pelvis and upper parts of femurs three months after hibernation. Note the rapid extension of the metastases, especially in the right ilium and femur. A plaster of paris cast of the leg and pelvis had been applied six weeks previously. The cast was removed, the roentgenogram taken and a new cast applied at this time (Dec. 19, 1939).

because it was feared that the patients would have a dreadful remembrance of the cold, but Fay's observations⁵ led me to use but little sedation after the temperature was down.

The procedure of hibernation is a very precarious one and should not be undertaken without adequate preparation and thought. The patient's family should be informed that death may occur at any time during

The nursing care is very exacting. Rectal temperatures, pulse and respirations are taken and charted at half hour intervals; almost constant blood pressure readings must be taken. Sometimes six special nurses are required in twenty-four hours, and the expense incurred for this service is great and in some instances almost prohibitive.

Fig. 9 (case 4).—Appearance of the pelvis and upper parts of the femurs five months after hibernation with a plaster of paris cast. Note the metastatic extension and the pathologic fracture (Feb. 2, 1940). (Serial roentgenograms of patient 1 reveal similar progressive metastatic extension.)

hibernation. Patient 6 in my series, with a temperature of 87 F., suddenly stopped breathing and the heart stopped; it was only by heroic measures instituted by the intern in attendance that vital functions were

Fig. 10 (case 5).—Temperature, pulse and respirations during thirty-six and one half hours of hibernation.

resumed. We lost no patients during the hibernation, but it required constant attention by either a resident, an intern or myself, as well as the help of a graduate nurse and the floor nurses.

TABLE 1.—Basal Metabolic Rates

Case	Basal Metabolic Rate Before Hibernation	Basal Metabolic Rate During Hibernation	Comment
1. S. H.	— 9%	—32%; temperature 88.1 F.	Basal metabolic rate taken after 35 hours of temperature under 95 F.; after hibernation basal rate —9%
2. N. S.	+45%	—36%; temperature 84.2 F.	Basal metabolic rate taken after 36 hours of temperature under 95 F.
3. R. O.	— 7%	—37%; temperature 86.4 F.	Basal metabolic rate taken after 29 hours of temperature under 95 F.
4. H. G.	+ 7%	—4%; temperature +88.2 F.	Basal metabolic rate taken after 20 hours of temperature under 95 F.
5. J. D.	+30%	+28%; temperature 87.4 F.	Basal metabolic rate taken after 15 hours of temperature under 95 F.
6. D. G.	Not determined	Not determined	

The pulse and respirations usually run a smooth and even curve, as shown by the accompanying graphs, until the end of the hibernation, when the temperature

Fig. 11 (case 6).—Temperature, pulse and respirations during nine and one half hours of hibernation. Note the gap in the graph where the pulse and respirations ceased. Heroic resuscitation methods revived the patient. He was allowed to come out of hibernation for fear of death during treatment. His symptoms were not relieved and he died at home three weeks after hibernation, apparently from cachexia. Consent for necropsy was not obtained. This illustrates the dangers associated with this treatment.

is allowed to return to normal. Invariably the pulse rate then becomes very fast, sometimes reaching 160 to 180. This is the most dangerous time of the whole procedure and is the time when death is most likely to occur from peripheral vascular circulatory failure.

COMMENT

Little clinical research has been done on human beings with a temperature below 95 F. from the standpoint of physiology or physiologic chemistry. For that reason I undertook to make a few superficial observations. In all cases except the last the basal metabolic rate

was determined before and during hibernation, an attempt being made to determine the rate at the lowest possible temperature. The results of these tests are listed in table 1.

In case 2, with a rectal temperature of 84.2 F., the basal metabolic rate was —36 per cent, while before hibernation it was +45 per cent.

Blood chemistry determinations were made in most cases before and during hibernation and in some after recovery from the hibernation, as may be seen in table 2. An interesting observation was that the blood sugar was high while the nonprotein nitrogen and urea were decreased in the majority of cases.

TABLE 2.—Blood Chemistry Determinations

Case	Time Relative to Hibernation	Temperature, F.	Date	Non-protein Nitro-gen	Urea Nitro-gen	Sugar	Chlo-rides	Great-ine
1. S. H.	Before		8/ 2/39	17.0	8.3	153

	During	87 rectal	10/20/39	45.0	0	180	470
	After							

The hemoglobin and red blood cells were increased, as would be expected, as the result of dehydration. The reticulocytes were increased during the hibernation period. The results of blood counts on these patients

The bowels did not function in any of the cases during hibernation. Catheterized specimens of urine were obtained every twelve hours. The amount of urine obtained gradually decreased every twelve hours unless fluids were given. The temperature of the urine was usually from 1 to 5 degrees lower than the rectal temperature, which was an interesting observation.

The illustrations show pulse, respiration and temperature charts of the six patients hibernated and roentgenographic appearances of two of these patients.

REPORT OF CASES

CASE 1.—S. H., a woman aged 52, had metastatic carcinoma of the bones from primary carcinoma of the breast. She is living eight months after treatment, with great relief of pain; no narcotics have been necessary. However, she had high voltage roentgen therapy before and snake venom after hibernation.

CASE 2.—N. S., a woman aged 38, had metastatic carcinoma of the bones from primary carcinoma of the breast which was removed by radical mastectomy four years previously. She died three days after hibernation, probably from peripheral cardiovascular collapse, since autopsy revealed no apparent cause of death. Pneumonia was not a cause of death in this or any of the cases in which autopsy was done.

CASE 3.—R. C., a woman aged 32, had metastatic carcinoma of the bones from primary carcinoma of the breast. She reacted unfavorably while undergoing treatment, as noted. She died seven days after hibernation; permission for necropsy was not obtained. She was generally debilitated and her life expectancy was short before treatment.

CASE 4.—H. G., a woman aged 26, had metastatic carcinoma of the bones from primary carcinoma of the breast, which was removed by radical breast amputation two years previously. She is living seven months after treatment; pain was relieved for the first three months in spite of pathologic fracture of the femur. She suffers from pain now, requiring codeine by mouth occasionally. She had some high voltage roentgen therapy before hibernation.

CASE 5.—J. D., a woman aged 30, had primary carcinoma of the cervix, grade 3, with generalized carcinomatosis. She

before, during and after hibernation are shown in table 3. Sedimentation readings were taken in some cases with greatly reduced temperature, and these are also shown. Electrocardiographic studies were made in some cases. Blood pressure readings were generally low and in some instances the systolic pressure reached as low as 70.

died twenty-four hours after completion of hibernation. Necropsy revealed cerebral edema as the cause of death. The pathologic changes in kidneys and ureters secondary to carcinoma of the cervix could easily have been responsible for the cerebral edema.

CASE 6.—D. G., a man aged 32, had primary carcinoma of the sigmoid colon with generalized carcinomatosis; a colostomy was done in February 1939 (fig. 11).

SUMMARY

1. Six patients with hopeless metastatic carcinoma, ranging in age from 26 to 52 years, have been hibernated.

2. The lowest temperature obtained was 83.2 F. rectal.

3. The hours spent in hibernation ranged from nine and a half to fifty-four and a half. The serious condition of the patient accounted for the shortness of the nine and a half hour hibernation.

4. Basal metabolic rates were determined at the submerged temperature, the lowest being 84.2 F. rectal; the metabolism was lowered in every case in which the determination was made.

5. Primary carcinoma of the breast with metastases in the bones was the diagnosis in four of the six cases; generalized carcinomatosis of the abdomen from primary carcinoma of the cervix and sigmoid colon accounted for the other two.

6. No deaths occurred during hibernation; four patients died between twenty-four hours and three weeks after hibernation.

TABLE 4.—Summary of Cases of Hibernation

Case	Sex	Age	Diagnosis	Hours Under 95 F.	Results
1. S. H.	♀	52	Metastatic carcinoma of bones; primary carcinoma of breast; breast not removed	43½	Marked relief for 2 months; living 8 months; metastases progressing
2. N. S.	♀	38	Metastatic carcinoma of bones; primary carcinoma of breast; breast removed 4 years previously, radical operation	51½	Death 3 days later
3. R. C.	♀	32	Metastatic carcinoma of bones; primary carcinoma of breast; breast not removed	40	Death 7 days later
4. H. G.	♀	26	Metastatic carcinoma of bones; primary carcinoma of breast; removal of breast 2 years previously	31½	Relief of pain for 3 months; living 7 months; metastases progressing
5. J. D.	♀	30	Primary carcinoma of cervix, grade 3, 6 months' duration; generalized, carcinomatosis	36½	Death in 24 hours from cerebral edema
6. D. G.	♂	32	Primary carcinoma of sigmoid; generalized carcinomatosis	9½	No relief; death in 3 weeks

7. Two patients are still living seven and eight months respectively after hibernation; they were entirely free from pain for three months and at present no narcotics are necessary to relieve their discomfort.

8. Roentgenographic studies reveal that the metastatic bone lesions are gradually progressing (figs. 6, 7, 8 and 9).

9. High voltage roentgen therapy had been given to all patients before hibernation.

10. Necropsy was performed on two of the four who died; cerebral edema accounted for one death, but nothing tangible could be found to account for the second death. Pneumonia was not a cause of death in any case.

CONCLUSIONS

A state of subcritical temperature was induced in six cases and certain physiologic changes were observed.

The relief of pain was the only result of possible value found in the two patients still living; but it should be noted that these patients had had high voltage roentgen therapy preceding hibernation which might in some degree be responsible for the relief of pain.

X-ray evidence reveals that one hibernation has not retarded the metastatic skeletal growth of carcinoma in these cases.

In my opinion this procedure is hazardous and is not justifiable in the treatment of hopeless metastatic carcinoma.

Animal experimentations in this field might be of value as a preliminary to any future use of hibernation therapy for human cancer.

Clinical Notes, Suggestions and New Instruments

CARDIAC MANIFESTATIONS FOLLOWING ERGOTAMINE TARTRATE THERAPY FOR MIGRAINE

J. BAILEY CARTER, M.D., CHICAGO

Since the isolation of ergotamine tartrate by Stoll¹ in 1918, enormous quantities have been used clinically. All available reports, analyzed by von Storch² for untoward effects of ergotamine tartrate therapy, revealed only forty-two serious sequelae, including eight fatal cases. Twenty-three occurred in obstetric cases, eleven in thyrotoxicosis and eight in miscellaneous disorders. This review also revealed that overdosage, and/or associated sepsis, obliterative vascular disease and/or cardiovascular disease play an important role in the production of ill effects. Death occurred in only one case³ unassociated with any of these factors.

Cardiovascular disease as a contributing factor is emphasized by Zimmermann,⁴ who reported that a patient having anginal attacks was given one 0.5 mg. dose subcutaneously and died an anginal death. Labbé⁵ gave a patient with organic heart disease a 0.5 mg. dose subcutaneously, daily for three days, with angina three hours after each dose and hemiplegia three days after the last dose. In a similar case, one 0.5 mg. dose given subcutaneously was followed by "syncopal" death.⁶

Although overdosage appears responsible for most of the ill effects of ergotamine tartrate therapy, doses of 3 mg. daily for twenty-eight days⁷ and a daily 0.5 mg. injection for over eighteen months⁸ have been used without apparent harm.

The first definite laboratory demonstration of the stimulant effect of ergot on the peripheral arteries was given by Kobert.⁹ Histologic changes of ergotism, reported by von Recklinghausen¹⁰ and confirmed by Lewis,¹¹ have been observed by Yater and Cahill¹² and Gould, Price and Ginsberg¹³ to follow the use of ergotamine tartrate.

Pathologically, the changes associated with ergotamine tartrate poisoning are vasospastic obliteration of the arteries.

intimal edema and hyperplasia, hyaline degeneration and thickening of the vascular walls, lymphocytic infiltration and frequent thromboses.

Significant symptoms suggestive of ergotism are those of (1) vascular occlusion, i. e., peripheral pain or paresthesias, coldness, cyanosis or blanching of the extremities, and (2) coronary occlusion, i. e., precordial pain or oppression and pain or paresthesia of the arm. Recurrence or persistence of these symptoms necessitates immediate search for organic pathologic change.

Ergotamine tartrate for the relief of migraine was first reported by Maier¹⁴ in 1926. Although the drug has no prophylactic value,¹⁵ it is the most effective¹⁶ specific¹⁷ treatment known for migraine. Results in recurrent attacks are just as dramatic and conclusive as when the drug is first used.¹⁸ It has given prompt relief of attacks in 90 per cent of more than 300 cases.¹⁹ Its use as an effective means of aborting or terminating migraine headaches has greatly increased. No ill effects from the use of ergotamine tartrate in migraine have been reported. The following report should therefore be of interest:

REPORT OF CASE

Mrs. R., aged 36, married fifteen years and five years a widow, contracted headache about 4 p. m. March 26, 1938. A physician gave a hypodermic of unknown content, without relief. At 1 a. m. March 27 0.5 mg. of ergotamine tartrate was given intramuscularly, and immediately palpitation, tachycardia, severe substernal distress and precordial pain with tightness in the throat developed, the headache being unrelieved. Thirty minutes later, one-third grain (0.02 Gm.) of pantopon was given hypodermically without relief. At 4 a. m. all complaints persisted in their original intensity. Auricular fibrillation was present with a ventricular rate of about 120 per minute. Administration of pantopon one-third grain was repeated hypodermically. At 6 a. m. the heart suddenly reverted to normal sinus mechanism. On disappearance of palpitation the patient slept between three and four hours. At 10 a. m. the precordial distress was less but moderately severe. The pulse rate was 72 and the rhythm regular. The heart borders were within normal limits by percussion. No murmur, no thrill and no other significant change were noted. An electrocardiogram made at 7 p. m. March 27 revealed nothing remarkable, and another record April 4 revealed, by comparison, no variation of significance. She has had no further trouble with her heart. A similar injection, one month previously, had resulted in substernal oppression without relieving the headache. The patient, 5 feet 2 inches (157 cm.) tall and weighing 102 pounds (46 Kg.), of feminine habitus, anxious and neurotic and with evidence of vasomotor instability, had measles, chickenpox and scarlet fever during childhood, typhoid in 1915, a tonsillectomy in 1916 and influenza in 1918. She has had recurrent headaches repeatedly diagnosed as migraine (?) since 1927, and hay fever from 1929, which was completely relieved by injections over a period of three summers. Appendectomy was done in 1930. Since 1935 sinusitis has complicated the symptomatology, confused the diagnosis and interfered with the therapeutic results of the headache. Owing to the dyspnea of allergic asthma associated with the hay fever in 1929, and preoperatively in 1930, the patient had submitted repeatedly to dental, ophthalmologic, gastrointestinal and extensive cardiovascular examination by various physicians, including several cardiologists, without significant observations.

For eight years the headaches occurred every two or three weeks. Since 1935 they have occurred daily. Chiefly frontal, they also involved the temporal regions, rarely alternating and

never generalized. Blurring of vision just before and near the end of an attack (at the height of the pain) occurred, but not constantly. Severe pain in the left eye occurred frequently. Lacrimation has been more constant. Nausea has been constant, the attack clearing up after the vomiting of bile. She insists that the only variation in the headaches since the onset of sinusitis in 1935 has been their frequency with daily occurrence. She also states that if she becomes nervous or excited or worried, especially when tired, she can develop, within half an hour, a headache indistinguishable from that described, all the characteristics being present even to nausea and vomiting with relief. No history of recurrent headaches, epilepsy, mental disease or allergy in the parents or grandparents was elicited.

COMMENT

Failure of relief by ergotamine tartrate is against a diagnosis of migraine.¹⁷ "The physiologic effects of a subcutaneous injection of ergotamine tartrate do not occur until ten minutes or more after injection—never immediately. Psychogenic reactions do. Ergotamine causes bradycardia by ten to twenty beats, rarely tachycardia. All these symptoms are those of acute anxiety—excepting auricular fibrillation."²⁰

Although the diagnosis of migraine appears doubtful and other possible etiologic factors cannot be eliminated, a distressing situation developed following an injection of ergotamine tartrate for headache. Care should be exercised in establishing the diagnosis of migraine.²¹ Use of ergotamine tartrate should be limited to migraine. It should not be used indiscriminately in the treatment of headache. Care should be exercised in the administration of ergotamine tartrate,²² even in small dosage and for migraine, since it can cause distressing and perhaps serious sequelae in the absence of the commonly recognized contraindications,² the result of individual susceptibility to the drug.²² This may help to avoid unfair criticism and undue fear of the drug, which may result from reactions following its improper use.

HEMOPHILIA TREATED BY VENESECTION

GEORGE B. LAWSON, M.D., ROANOKE, VA.

AND

A. B. GRAYBEAL, M.D., MARION, VA.

In March 1931, as already reported,¹ a man aged 51 acutely ill with hemophilia was treated by venesection. In forty-eight hours he was almost free from symptoms. For long intervals he had been completely incapacitated because of joint symptoms occurring with the hemophilia. After this the patient, on the onset of symptoms, would come in for venesection on an average of about once every six weeks. From 400 to 500 cc. of blood was removed each time. The last venesection done by us was on June 23, 1939, when he was apparently in good physical condition except for nervousness and marked apprehension of death. He had been in rather good condition as a whole during the many years that we had been bleeding him, except for some discomfort in one knee. The x-ray film of this knee showed small cystic looking areas in the patella and lower femur.

He was admitted to a government hospital and its report is as follows:

"May 17, 1939: 300 cc. of blood withdrawn this date with improvement for nervousness, eye twitches, etc.

"June 10: Patient getting along well. Has had no bleeding episode as yet. Calm, not as nervous as before and feels O. K.

"June 21: To furlough this date at own request.

"July 16: Admitted to hospital. Returned from furlough this date. General condition same.

"July 17: To barracks this date.

"August 13: Patient readmitted to hospital this date appearing acutely ill with swollen right knee and leg. This is extremely painful on walking. Examination: Patient's face

and body covered with a beady cold perspiration. Skin clammy and patient extremely 'shaky.' Right knee and leg are swollen, tender, hot and very painful on motion even to the examining finger. Diagnosis: Hemorrhage into right knee joint.

"August 15: Patient has a large submental swelling pushing up floor of mouth, which is enlarged, deep and red looking, interfering with speech and swallowing. Probably is still bleeding in soft tissues of neck. Pulse is full and strong but condition doesn't seem very good; 275 cc. of blood under great pressure, removed.

"August 16: Patient seen this a. m. Appears seriously ill. Lower jaw and floor of mouth frozen, apparently with hemorrhage of yesterday evening. Patient dull, listless, cold and clammy. Pulse is 84 and weak. Respirations apparently normal. Right knee stopped hemorrhaging two days ago. Venesection with removal of 275 cc. last p. m. Some improvement reported following treatment. Patient seen again at 3 p. m., restless, semiconscious, pulse of 120 per minute, dry and complaining of very deep thirst. Believe condition generally remains same and that there is still some oozing in tongue. Will give 1,000 cc. 5 per cent dextrose by hyperdermoclysis to allay apparent dehydration. At 8 p. m. condition is poor. Tongue and floor of mouth enormously swollen and deeply hemorrhagic in color (color that of liver). Blood in neck is beginning to discolor the soft tissues. Patient is unable to talk or to swallow; makes known his wishes by pencil and paper. Is extremely anxious over his own condition to point of being frantic."

He died on Aug. 17, 1939, "death being due to massive hemorrhage and contributory cerebral edema."

In January and March 1938 we² treated two other hemophilic patients by venesection, with remarkably good results. One of these, a nephew of our first patient, was a boy aged 10 years. This boy did well until Feb. 8, 1939, when acute pain developed in the left sacro-iliac region. This pain became rapidly worse. Nine days from the onset, anesthesia and complete paralysis developed from the waist down. There was also paralysis of the rectum and bladder. There were a high fever, blood in the urine and subcutaneous hemorrhages.

Lumbar puncture was done February 19, two days after the onset of complete paralysis. The spinal fluid was not under increased pressure and microscopic examination showed only a few red blood cells. In the beginning venesection was performed but was apparently not helpful. This picture of sickness with paralysis, irregular fever, subcutaneous hemorrhages and bloody urine continued for seven weeks before death occurred.

CHYLOUS PERITONITIS

ROLAND L. MAIER, M.D., NEW YORK

History.—A man aged 41 when seen March 16, 1939, gave a history of having been in perfect health on retiring the night before. He was awakened at 1 a. m. with severe abdominal pain about the umbilicus. The pain was constant but there was no nausea or vomiting. The hotel physician was called; he diagnosed the condition as acute appendicitis and advised immediate operation. He gave the patient one-fourth grain (0.016 Gm.) of morphine for the pain. When seen by me, the patient had had the hypodermic and the pain had been greatly relieved, but he looked acutely ill and was perspiring freely. He vomited once half an hour after the morphine had been administered. The temperature was 99 F. by mouth. The abdomen had a boardlike rigidity, and slight pain on pressure was elicited just to the left of the umbilicus. The patient was removed to the hospital, where flat plates revealed no air under the diaphragm. The white count was 10,800, with 56 per cent polymorphonuclears. While the latter procedures were being done, the pain began to recur with its previous intensity, and immediate operation was deemed advisable. The pre-operative diagnosis was perforated ulcer or mesenteric embolus. There was no history of trauma.

2. Lawson, G. B., and Graybeal, A. B.: Hemophilia Treated by Venesection, *J. A. M. A.* 111: 2104-2105 (Dec. 3) 1938.

The patient had three attacks of rheumatic fever, at 6, 16 and 18 years of age. A tonsillectomy was performed in 1918. These attacks of rheumatic fever left the patient with a double mitral lesion. His heart had always been well compensated and he had always been able to do his regular work. He had taken no medication for his heart at any time and never had any cardiac symptoms.

Operation.—A right rectus muscle splitting incision was made, and when the peritoneal cavity was opened the lacteals of the small intestine were seen to be very prominent and distended; this was twelve hours after he had eaten dinner. The mesentery about 12 inches from the ileocecal junction was covered with milky exudate for a distance of 3 or 4 inches. This area of mesentery was greatly thickened and somewhat contracted. A small amount, about 20 cc., of milky looking fluid was found in the dependent portions of the peritoneal cavity. This was aspirated and sent to the laboratory for culture and smear. The remainder of the gastrointestinal tract was normal in appearance. No perforations were found and the appendix appeared normal. Since the appendix presented itself in the wound, an appendectomy was performed. The pancreas seemed of normal consistency and there was no evidence of fat necrosis. The abdomen was closed in layers, one rubber dam drain being left at the lower angle of the wound down to the peritoneum.

Postoperative Course.—After the operation the patient was given pitressin every four hours in hopes of preventing post-operative distention. The day after the operation fibrillation set in and the abdomen became distended. Digitalization was quickly instituted and his pulse rate was brought down from 140-160 to 80-85 and kept there by maintenance doses of digitalis. The distention persisted for three days. The stomach was repeatedly lavaged, large amounts of gastric contents being removed each time, and finally the Levine tube was left in constantly. After five days his convalescence was uneventful. The superficial drain was removed in forty-eight hours. Digitalis was discontinued after ten days.

The patient has had no symptoms of any kind since operation and returned to work six weeks from the date of the operation. There is a slight weakness in the abdominal wound as a result of the distention, which broke three or four retention sutures. Laboratory examination of the peritoneal fluid showed no organisms, and a smear revealed only fat droplets.

COMMENT

In a search of the literature no record of a similar case has been found. Allan and Heggie¹ report a case of chylous peritonitis in which there had been a rheumatic heart condition since childhood and in which ascites developed periodically; in the course of years forty paracenteses were performed. The fluid aspirated each time was chylous. This case was fatal and autopsy revealed a fibrotic short, thickened mesentery. Brown² in January 1937 reported a case of chylous peritonitis following traumatic rupture of the thoracic duct. Nowhere have I been able to find a report of an acute case such as the one presented here. The conditions found at operation suggest that there was a rupture of one of the lacteals caused by obstruction of the thoracic duct, with back pressure on the smaller lacteals. This would seem plausible in view of the extreme distention of all the lacteals as seen at operation, and the plausible site of rupture was at the greatly thickened and contracted mesentery seen near the ileocecal junction. Whether or not the condition will recur remains to be seen, but to date the patient has had no symptoms of any kind. It is obvious that the operation had little to do with the patient's recovery, but in view of the possibility of a perforation of the intestinal tract it would have been extremely difficult to withhold operation.

Special Article

CONFERENCES ON THERAPY

TREATMENT OF BLOOD DISORDERS

II. THE USE OF IRON AND OTHER METALS

NOTE.—These are actual reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with the collaboration of other departments. The questions and discussions involve participation by members of the staff of the college and hospital, students and visitors. The next report will concern "Treatment of Blood Disorders: III. The Use of Transfusions."

DR. McKEEN CATTELL: We shall continue our general topic, treatment of disorders of the blood, with special reference to the therapeutic use of mixtures of metals and the effects of copper in relation to iron therapy. We shall hear first from Dr. Summerson, who will discuss the chemical and physiologic basis for the use of metals other than iron.

EXPERIMENTAL ASPECTS

DR. WILLIAM H. SUMMERSON: When one speaks about the value of metals other than iron in the therapy of anemias, interest is primarily directed to copper because of the demonstration that copper is associated with iron in the formation of hemoglobin in the animal body. This was experimentally established about a decade ago, and although it was challenged at the time the facts have withstood all attempts to break them down. I think that no one seriously questions nowadays, from a biologic point of view at any rate, the significance of copper in the processes of hemoglobin formation in the animal body.

The significance of copper in hemoglobin formation has been clearly demonstrated in a variety of animals such as the rat, the rabbit, the pig, the chicken, the sheep and the dog. Although a requirement for copper has not been conclusively demonstrated in the human being, it seems quite reasonable to expect that what is true for lower animals is also true for man. The difficulties of experimental demonstration in human beings obviously preclude any such conclusive demonstration as is possible in the case of experimental animals.

The mode of action of copper in the formation of hemoglobin is entirely unknown. The amounts of copper required are very small and out of all proportion to the amounts of iron that are converted to hemoglobin in the presence of copper. Thus far the only significant facts that have been demonstrated with regard to the way copper acts in the body are that it apparently does not influence either the absorption of iron or the storage of iron in the body but that it aids in the mobilization of stored iron and facilitates the conversion of stored iron into hemoglobin.

Because of the small amounts of copper required by the organism, attention has been directed to a possible catalytic action of copper on hemoglobin synthesis. Two possibilities suggest themselves in this connection. There is the possibility that a copper-containing, intermediate compound is necessary in the chain of reactions leading to hemoglobin synthesis and that copper is subsequently split off and the molecule ultimately built up into hemoglobin. There is also a possibility that copper is an activator for a specific enzyme system that is associated with the formation of hemoglobin in the

body. No conclusive evidence for either of these theories has as yet been adduced.

As I stated, there has been no clearcut demonstration of the necessity for copper in the formation of hemoglobin in the human being. The difficulty is probably due to the fact that the amounts of copper required by the organism are quite small, and it is difficult to control the experimental diet of the human being in such a way as to produce a copper deficiency. It has been shown that copper is present in small quantities in practically all foods, and a computation of the copper content of normal human diets has demonstrated that the dietary intake of copper varies, depending on the type and amount of food eaten, from about 0.8 mg. of copper a day for children to about 4.8 mg. a day for adults.

How much copper does the human organism need? One way to get an answer to that question is by copper balance studies. On the basis of such studies it has been estimated that children require as an optimal daily intake about 0.1 mg. of copper per kilogram of body weight. If you take that as the average daily requirement of copper for the human being, you can see that a 70 Kg. man would require 7 mg. of copper a day. I just cited 4.8 mg. as the daily copper intake on an average diet, so there is not a great discrepancy between the copper needs of the human being and the amount of copper that he gets in the diet. The possibility arises, and this is suggested I think by clinical experience, that there may be a chronic copper deficiency, that is, a state in which small amounts of added copper would be of value. This accords with the clinical experience that small amounts of added copper are sometimes of value.

The best results from the use of copper in the therapy of hypochromic anemia in the clinic have been obtained in the anemias of infancy, and there are increasing numbers of case reports in the literature which show, but by no means conclusively, some effect associated with the addition of copper to iron in the therapy.

With regard to the treatment of hypochromic anemia occurring in adults, the evidence is even less impressive, probably because it is so much more difficult to produce a copper deficiency anemia in the adult than in the young growing organism. However, it has been reported that certain cases of stubborn hypochromic anemia relatively resistant to iron administration have responded more favorably to the addition of copper along with the iron than have controls to whom iron alone was administered. All of these results are complicated by the fact that practically all commercial iron preparations contain varying amounts of copper, and I think that in no case in the clinic have the experimental conditions been as carefully defined as in the laboratory. Naturally clinical definition is less feasible.

The general view at the present time with regard to the clinical value of copper might be summed up as follows: Most patients with hypochromic anemia seem to require no added copper and get along perfectly well with an ordinary iron salt, yet there is also a certain proportion of cases in which the addition of copper along with the iron seems to lead to greater increases in the hemoglobin level in the blood than without the added copper.

Another element has become of interest in the last few years with regard to hemoglobin formation, and that is cobalt. Cobalt will not replace copper in the usual experimental animals; that is, in the rat and in certain other animals it has apparently no influence on

hemoglobin formation. It is certainly not comparable to copper in the rat. But it has been shown to be entirely comparable to copper in one species, namely, sheep. There are a number of areas throughout the world where sheep suffer from a sickness which is known by various local terms but which is almost invariably characterized by an anemia similar to chlorosis. It has been shown that the addition of neither iron nor copper to the diet will cure this anemia but that the addition of small amounts of cobalt will bring about a rapid and complete cure. So far as I know that is the only experimental demonstration of the value of cobalt in hemoglobin synthesis in nutritional anemia. Cobalt has, however, another action which is of interest, namely, that in the normal animal it produces a polycythemia. That fact has proved of some value in the study of experimentally induced polycythemia in animals. The significance of cobalt in the treatment of clinical anemias I think is quite indefinite at the present time. The chief interest in this metal is associated with the demonstration that at least in one species cobalt is an essential element for the conversion of iron into hemoglobin. There is also the interesting fact of the marked stimulation of the bone marrow associated with cobalt administration leading to an experimental polycythemia.

DR. CATTELL: Are there some questions we might put to Dr. Summerson now?

DR. HARRY GOLD: Do I understand that hemoglobin formation does not go on in the absence of copper?

DR. SUMMERSON: That is certainly true for all the animals that I listed.

DR. CLAUDE E. FORKNER: But it may go on in the presence of other elements? Will not other elements substitute for copper?

DR. SUMMERSON: I don't believe so. That was one of the points that was brought out at the very beginning of the work on copper. I think most people agree that stimulation due to other elements than copper is minimal, if present at all, and, if it is obtained, that it is probably due to contamination with copper in the preparations.

DR. GOLD: Are arsenic and manganese out of the question now as substitutes for copper?

DR. SUMMERSON: That is a very interesting question. In one series of experiments arsenic was the only element aside from copper that showed a very slight stimulating action, but it did not compare with that following copper. As far as we know, manganese has no function in hemoglobin formation, but there is no doubt that it is necessary for normal growth.

DR. PAUL REZNIKOFF: What about germanium? That was long considered an important element.

DR. SUMMERSON: Its importance certainly does not apply to the rat.

STUDENT: Have these sheep you mentioned been put on a copper deficient diet? In other words, was cobalt a substitute or was there some additional factor?

DR. SUMMERSON: On a milk diet lambs—I always refer to young animals—develop an anemia. This is cured by the addition of copper along with iron to the diet. At the time these experiments were made, the significance of cobalt was not realized. In the experiments I mentioned a little while ago it was found that the presence of iron as well as copper in an otherwise

adequate diet for the pastoral lamb had no influence on the disease, but that cobalt had to be added along with the iron.

STUDENT: Is that taken as evidence that the cobalt acts as a direct substitute for the copper?

DR. SUMMERSON: I would say that you can demonstrate in one type of experiment that the animal needs copper. You can demonstrate in another type of experiment that he also needs cobalt. It seems to me that the evidence indicates a need for both cobalt and copper along with iron in the case of the sheep.

DR. FORKNER: I should like to ask Dr. Summerson whether in his experiments there has been any indication that copper produces any untoward effects, perhaps over a long period of time. I think a great many clinicians hesitate to use copper because they fear some possible toxic effect. I am thinking, for instance, of Mallory's work on hemochromatosis.

DR. SUMMERSON: That is always a possibility, but the amounts of copper that one gives are very small. Animals have been maintained on a mineralized milk diet, that is, milk plus copper, iron and manganese, for long periods and they appear to be quite normal on that diet. No one has ever detected any pathologic effect of copper in the amount that is ordinarily sufficient to stimulate maximal hemoglobin formation. If large amounts of copper are given, then of course it is quite toxic.

IRON, COPPER, COBALT, MANGANESE, GERMANIUM, NICKEL

DR. CATTELL: Dr. Reznikoff, will you discuss from a practical standpoint the use of the several metals which have been mentioned?

DR. REZNIKOFF: As Dr. Summerson has pointed out, most of the work—and I think probably the best work—on the value of copper and cobalt in anemias and other conditions affecting the blood has been done on animals.

Among the workers who have studied human beings, mostly children, Sachs, of Omaha, I believe has contributed the most careful quantitative work. Sachs and his co-workers came to the conclusion on the basis of the determination of copper and iron in the blood of children that there was a reciprocal relationship between these two metals in the blood; that is, when iron was increased copper was decreased, and vice versa. Not only was that true of the anemias, but they found that the relationship also held in a few cases of polycythemia; that is, as the blood count in polycythemia decreased under treatment, the iron content of the blood decreased but the copper content increased. They postulated that copper may be mobilized as a stimulator of hematopoietic activity. They also felt that it acted in the capacity of an emergency oxidative catalyst. This suggests that copper is not an essential part of the structure of hemoglobin but, as Dr. Summerson has pointed out, really a catalyst.

With regard to adult patients we are confronted with problems which are not easy of solution. We can accept the experimental work on animals, but with practically all of our patients we cannot find that any of these adjuvants are of any significance. The probability is that the principle holds true that copper is necessary for the development of a normal hemoglobin content in the red blood cell; but, possibly because the necessary amount of copper is so small that it is always supplied in food or medication, or for other reasons, the fact

remains that in adult hematology we never find it necessary to give copper to a patient. There are products on the market which contain copper and iron, but I do not know of any case in which I felt copper should be administered, and I do not know of any reports in the literature which make it clear that without copper the anemia of adult patients would not have been cured.

As for metals other than iron and copper, Kato, at least in his work up to 1937, felt very strongly that in infants cobalt could act as a definite accelerator of red blood cell and hemoglobin formation. He felt it was necessary for both, but there again he assumed that cobalt was just a catalyst. There are some workers, and I think Elvehjem is one of them, who think that manganese can be ranked as an equivalent of copper so far as rat growth is concerned; however, they do not commit themselves as to the role of manganese in the formation of hemoglobin. There are suggestions throughout the literature that manganese, cobalt, germanium and perhaps nickel can simulate the action of copper but in much less degree, and thus there would be only a quantitative difference. For practical purposes copper is the most effective, but perhaps we should not exclude entirely the possibility that these other elements may have some effect on hemoglobin formation.

In the literature on the effect of copper and cobalt in anemia, I have not found what I could call a crucial experiment, and that would be this: When you give iron to an iron deficient patient who has an anemia, there is a reticulocyte rise of varying degree before the hemoglobin begins to rise. Some time after the reticulocyte count returns to the base level or establishes a plateau, copper should be administered to see if there is any secondary reticulocyte effect. If a secondary reticulocyte rise is produced, this would be fairly good evidence that an extra stimulant was thrown in which was not present when iron alone was given, or iron plus the contaminations.

Our interest in cobalt in adult patients centers not so much in anemia as in polycythemia. As Dr. Summerson has said, there has been a good deal of work on the effect of cobalt in polycythemia, but that it plays any role in this condition has been shown only with regard to animals. With the polycythemic patient studies of the blood show that there is not any increase in the new red blood cells as the result of cobalt, if we take reticulocyte counts as a gage; also, if we examine the bone marrow, no increase in the number of immature cells is seen. The Barrons found that the administration of ascorbic acid prevented the cobalt experimental polycythemia, and therefore they postulated that ascorbic acid is one of the regulators of hematopoiesis. We accept the fact that ascorbic acid is a regulator of hematopoiesis, but our experience has been that if vitamin C is withheld an anemia develops; in other words, ascorbic acid is, if anything, a factor in producing red blood cells and not in inhibiting red blood cell formation, as seemed to be the case in the experimental cobalt work. However, we may be dealing with two different functions; that is, cobalt may produce polycythemia in a different way than ascorbic acid produces a normal red cell response.

Davis has recently been working with polycythemia induced by cobalt chiefly in dogs. He found that if he gave liver extract, which must be unheated, or if he gave choline derivatives (I believe he used choline hydrochloride for the most part) he could prevent the

polycythemic effect of cobalt. Immediately clinicians began to use liver extract of the type that he mentioned for patients suffering from polycythemia. It was soon found by Major that it had no effect on polycythemic patients.

IRON AND COPPER DEFICIENCY IN THE INFANT

DR. CATTELL: Next I shall ask Dr. Smith to make a few remarks about the problems that arise in the treatment of anemia in children.

DR. CARL H. SMITH: The previous speakers have referred to iron or iron in combination with copper and other adjuvants in the treatment of the anemias of infancy and childhood. In discussing the need of added copper from a clinical standpoint, it should be noted that not all the striking results obtained with animals can be transferred directly to anemic infants and children. In spite of the fact that the nutritional anemia of infants closely resembles the iron deficiency anemia of laboratory animals induced by milk diets, the reports concerning the need of copper as a supplement for the anemic infant have been conflicting. It seems to me desirable, therefore, to review the problem of iron deficiency in the infant both as to its pathogenesis and as to its treatment with iron and other metals.

At birth, with the termination of anoxemia, the fetal polycythemia is no longer needed and destruction of red cells and hemoglobin occurs. Figures for the hemoglobin value at birth vary from 16 to 23 Gm. per hundred cubic centimeters, according to studies from various parts of the world. This variation probably depends on the climatic conditions and the racial, hygienic and dietetic factors prevailing in the particular localities where these studies were conducted. The most pronounced drop in hemoglobin occurs after the first week or ten days of life, after which the hemoglobin continues to fall until the age of from 6 weeks to 2 months, when a level is reached. Except for a slight rise occurring between 3 and 6 months, the hemoglobin level for normal children fluctuates within a narrow range during the first two years of life. The values for normal infants from the age of 2 months to the end of the first year, according to recent studies, range from about 10 to 12 Gm. of hemoglobin per hundred cubic centimeters of blood. Therefore, when we speak of nutritional anemia in infants we mean that the hemoglobin value is found to be consistently below this lower limit of 10 Gm.

The question has often arisen Should these values of from 10 to 12 Gm. be elevated? In obtaining an answer to this an inherent difficulty arises from the lack of data as to what the optimum hemoglobin value is; that is, what value will promote the greatest growth and development of the infant. Although we usually find that normal infants on adequate diets have an average hemoglobin value of about 11 Gm., it is possible by the administration of iron to boost this figure. For instance, Elvehjem and his associates were able to raise the hemoglobin value of normal infants from between 9 and 11 Gm. to 12 and 13.5 Gm. per hundred cubic centimeters of blood by the daily addition to their diets of 25 mg. of iron and 1 mg. of copper. It is not yet certain, however, whether it is desirable to maintain these higher levels and we do not know, for instance, whether raising the hemoglobin by routine iron administration will decrease the susceptibility of these infants to infection. Closely controlled observations would be

necessary to determine the advantage of the elevated hemoglobin with respect to morbidity, mortality and growth.

Since we do not have these facts, the range of hemoglobin values obtained for infants whose physical development measures up to normal standards should be used as the basis for comparison. As we have said, following the neonatal period the full term infant of average birth weight and in good nutrition as seen in private practice has an average hemoglobin of 11 Gm. or more, and we know that the majority of these babies get along perfectly well. For practical purposes, therefore, the value of 11 Gm. should be designated as the lower limit of normal. This is an arbitrary figure, however, and it is not unusual to encounter infants, particularly premature babies or twins, who appear normal in every respect but whose hemoglobin after the second month falls somewhat below this value.

What factors contribute to the development of a nutritional anemia in infancy? Particular attention should be directed to the hemoglobin level of all infants who are growing rapidly, to premature babies and twins, to those troubled by frequent infections, to those whose mothers during the latter part of pregnancy were known to have suffered from a profound anemia, and to infants who during the neonatal period were suffering from a blood dyscrasia such as primary anemia of the newborn or who have survived the condition of icterus gravis. Prolonged lactation or a diet largely of milk, especially when associated with the refusal of solid food, constitutes an outstanding cause of nutritional anemia. Until solid foods are introduced in the diet, the intake of iron and probably of other adjuvants concerned with hemoglobin synthesis is meager, and the young infant depends largely on prenatal stores and products derived from blood destruction for the fulfillment of its metabolic requirements.

Another question is "Can the initial sharp drop in the hemoglobin level after birth be prevented?" Many studies have been conducted with full term and premature infants in the endeavor to forestall the low hemoglobin levels reached at 6 weeks to 2 months of age by administering iron, with or without adjuvants, even as early as in the first weeks of life. It has been demonstrated that the reduction in hemoglobin occurring during the first six weeks of life could not be prevented, although the terminal level reached was not so low and the subsequent hemoglobin values were higher than in the untreated cases. The available evidence supports the conclusion that the early drop in hemoglobin is physiologic and due to intrinsic factors.

On the other hand, experience has shown that the hemoglobin level after the second and third months can be elevated by iron administration instituted at this time, and we usually begin treatment if the value falls below 10 Gm. per hundred cubic centimeters of blood. With premature infants and twins, hemoglobin determinations should be begun during the second month of life. With normal full term infants, these may be postponed until the third month. Nutritional anemia should be looked for in all infants of 6 months or over, since at this time iron stores are usually depleted, although it may develop earlier. Parsons has described cases occurring at or shortly after birth. By following closely infants whose hemoglobin fluctuates about the level of 10 Gm., carrying out tests at frequent intervals and instituting anti-anemic therapy if the same or lower values are consistently obtained, treatment is confined to infants

in whom an iron deficiency becomes apparent. This obviates the necessity for the routine administration of iron to all infants.

How should these babies with nutritional anemia be treated? While adequate food iron usually insures protection against the development of anemia in infancy, it cannot be depended on in treatment and an inorganic iron salt is essential for cure. The choice of the preparation for the infant as well as for the adult depends on its known activity, ease of administration, tolerance and inexpensiveness. In the case of the infant, the solubility also is particularly important, since inorganic salts that are readily ingested by an adult may be unsuitable for a baby. The iron salt preferably should be soluble. Reduced iron and saccharated ferrous carbonate, because of their insolubility, have the disadvantage of requiring suspension, but they can be given to older children. Although there are several soluble iron salts suitable for use in infancy, the efficacy of which has been amply demonstrated, my own experience has been with two of these, namely iron and ammonium citrates and ferrous sulfate. The former may be prescribed in a 10 per cent solution or in capsules. For the infant, the capsules must be opened and the contents dissolved in a suitable vehicle. It is important to emphasize that in administering iron to a baby one has to tell the mother exactly how it is to be given. One has to tell her specifically "Take the iron salt out of the capsule and put it in the baby's orange juice, milk or water." I once had the experience, however, of having a father call me up to tell me that after two weeks the baby had finally swallowed a capsule.

The dose of iron depends on a number of considerations. The absorption of iron from the intestine of the infant is subject to a variety of influences, in part similar to those of the adult and in part resulting from local conditions incident to its own stage of development. Therefore a specific dosage cannot be definitely assigned for a particular age. Furthermore, the dosage should be controlled by frequent hemoglobin estimations and the tolerance of the infant for the preparation. It is advisable to start treatment with a small dose, let us say 5 grains (0.3 Gm.) of iron and ammonium citrates, since at times vomiting or diarrhea follows its use. Should these untoward symptoms occur during the course of treatment, the quantity of iron may be temporarily reduced or another iron salt may be employed. In the infant with nutritional anemia of a moderate grade, the desired hemoglobin level can usually be obtained with a daily dose approximating 1 grain (0.06 Gm.) of iron and ammonium citrates per pound of body weight. Thus the total dose is usually from 15 to 30 grains (1 to 2 Gm.). With more severe anemias in older infants, 45 grains (3 Gm.) or more is sometimes required. With the continued use of the maximum dose, however, the urine should be examined for evidence of kidney irritation. In recent years we have employed ferrous sulfate almost exclusively. A daily dose of from 6 to 8 grains (0.4 to 0.5 Gm.) of this salt has been sufficient to produce a satisfactory reticulocyte response and the restoration of the normal hemoglobin, red cell and hematocrit levels within a period of from two to three weeks. The smaller dose required in the case of the ferrous salt has the advantage of minimizing the likelihood of gastrointestinal disturbances. It is prescribed in infancy in the form of an elixir, each teaspoonful containing 2 grains (0.13 Gm.) of ferrous sulfate or approximately 26 mg. of metallic iron. It must be emphasized that the most favorable

results with iron therapy in infancy are obtained by the exercise of skill in administration of these salts, and the possibility of refusal and of gastrointestinal upsets necessitates a familiarity with the use of more than one preparation. One cannot depend on one iron salt alone.

The next question is Should copper be used? In our experience it has not been necessary to employ copper in the treatment of nutritional anemia, although there are studies to show that its addition in minute traces results in prompt acceleration of hemoglobin production from a previously stationary level. The results on this point are conflicting. The studies of Elvehjem have already been referred to in which iron and copper raised the hemoglobin of normal infants as high as 13.5 Gm. per hundred cubic centimeters of blood, whereas hemoglobin levels of 14 Gm. were obtained by Stephenson with the use of iron salts without any copper supplements. For the occasional infant in whom copper deficiency may occur, as evidenced by a refractory state of the anemia, minute amounts of this element, 1 mg. daily (equivalent to 4 mg. of copper sulfate) may be included in the iron prescription.

Although achlorhydria sometimes accompanies iron deficiency in infancy, the administration of hydrochloric acid is without value. Parenteral liver preparations are also unnecessary.

DISCUSSION OF QUESTIONS

DR. CATTELL: The meeting is now open for general discussion. Are there some questions you would like to put to Dr. Smith?

DR. REZNIKOFF: I should like to ask Dr. Smith whether in his opinion the work published by Dr. Hugh Josephs at Johns Hopkins on babies who are recovering from pneumonia and have anemia is fairly conclusive. To all these anemic children he gave iron in rather large amounts and could get no rise in hemoglobin until he gave them copper.

DR. SMITH: It is true that Josephs obtained poor results with iron alone in some of his cases of convalescent pneumonia in infants, but the majority did show a definite response although a maximum rise in hemoglobin did not occur until copper therapy was instituted. My own experience is that iron therapy is unsatisfactory during the stage of acute infection, but once this has subsided then it is entirely effective without the addition of copper. The termination of infection is difficult to detect, and low grade fevers may persist without obvious cause. In such a case the lack of response to iron may prove of clinical importance. When iron in adequate doses—from 6 to 8 grains of ferrous sulfate daily—is administered to a young child with anemia of moderate severity, the absence of a reticulocyte response and a failure of the hemoglobin to return to a level of about 11 Gm. per hundred cubic centimeters of blood and of the hematocrit to reach a value of 36 per cent in from two to three weeks suggest continued activity of the infectious process or that the diagnosis of anemia on a purely nutritional basis is to be questioned. When anemia accompanies prolonged infection, even of low grade, it is more expeditious to treat the infant or child with blood transfusion than to temporize with iron.

DR. REZNIKOFF: Dr. Smith uses 6 grains of ferrous sulfate and that is equivalent to about 100 mg. of iron a day. It appears that with the infant as well as the adult larger doses of the ferric salt are given in order to obtain a satisfactory therapeutic effect.

DR. JANET TRAVELL: What is the usual dose of iron when given in the form of the ferric ammonium citrate?

DR. SMITH: For the ferric ammonium citrate we use the brown scales, which contain not less than 16 per cent of iron. The effective dosage for infants is roughly 1 grain of this salt per pound of body weight, which corresponds to 10 mg. of metallic iron per pound of body weight, does it not?

DR. TRAVELL: That is, for a 20 pound baby the usual doses would be 100 mg. of ferrous iron and 200 mg. of ferric iron. It is interesting that 100 mg. of iron is the dose used by Schlutz, Morse and Oldham in comparing the relative effectiveness of these same two iron salts, ferrous sulfate and ferric ammonium citrate, in nutritional anemias of infants. They found that 100 mg. of iron supplied as iron and ammonium citrates and 100 mg. of iron supplied as ferrous sulfate were equally efficacious.

DR. SMITH: We have found that at times even larger doses of iron and ammonium citrates may be required than the doses suggested. That caution must be exercised with the larger amounts was illustrated in our experience with an infant for whom the dose of iron and ammonium citrates was gradually raised to 90 grains (6 Gm.). With this amount kidney irritation occurred, manifested by an increased number of red cells and casts in the urine as determined by the Addis method.

DR. FORKNER: I think it ought to be pointed out that forty or fifty years ago very large doses of iron were given as compared with those we use now. Then as the result of the metabolic studies of Stockman and others demonstrating that little of this iron was utilized, smaller doses came to be recommended. For many years small and inadequate doses of iron were given, probably because the problem was attacked too scientifically, and only after about 1920 was it again discovered that large doses of iron had to be given in order to obtain an optimal effect.

DR. SUMMERSON: I think it is very interesting that the optimum dose of iron recommended by Dr. Reznikoff at our last conference is from ten to twenty times the amount of iron apparently required by the body, taking the average daily requirement as 15 mg.

DR. FORKNER: One point which Dr. Smith touched on was the element of infection. If a patient has fever or infection one can expect very little effect from iron or any other hematopoietic stimulating agent so that one has to take that factor into account. Frequently patients in the ward are given large doses of iron when they have an active infection and one wonders why they don't respond, but it is pretty clear that infection markedly inhibits the utilization of iron.

DR. REZNIKOFF: Dr. Forkner has brought up a very important point. In all this discussion we have to consider what is the condition of the patient. For example, it is fairly well agreed that the amount of iron utilized by the organism to produce hemoglobin depends to a considerable extent on the needs of the organism.

We once did an interesting experiment with potassium ferrocyanide. If one gives a normal animal potassium ferrocyanide, about 100 per cent is excreted in the urine. The same was true when we took it ourselves. None of the iron was apparently utilized. But an animal with an iron deficiency anemia is able to retain about one third of the iron given. That was a striking illustration of the fact that various factors like iron depletion, infection and many other conditions probably occurring in patients will determine the utilization of iron.

DR. TRAVELL: A striking experimental demonstration of the influence of need on utilization has been obtained recently by Hahn and his collaborators by following the course of a radioactive isotope of iron in the body. By this technic it is possible to distinguish between the newly absorbed iron and that previously present in any form or location. When Whipple's standard anemic dogs were fed radioactive iron, within twenty-four hours an appreciable amount had accumulated in the spleen, liver, bone marrow, red blood cells and blood plasma. About fifty to a hundred times as much iron was absorbed by the blood and viscera in the anemic animal as was absorbed in normal dogs or dogs rendered plethoric by blood transfusions, when similarly treated. The authors are inclined to believe that absorption is regulated selectively by the mucosa of the small intestine and not by the concentration gradient of iron existing between the gastrointestinal contents and the blood plasma.

SUMMARY

DR. CATTELL: In summarizing today's conference, the following points stand out:

Copper has been shown to play an important role in hemoglobin formation in a variety of experimental animals. All that is known regarding its mode of action is that in some way it facilitates the conversion of stored iron into hemoglobin. Although it is reasonable to assume that it has a similar function in hematopoiesis in human beings, it has been impossible to demonstrate this, except possibly in the nutritional anemias of infancy. The difficulties are these: First, the daily requirement of copper is very small and it is not feasible to control the diet so as to produce a copper deficiency; second, nearly all commercial preparations of iron contain copper in varying amounts, often enough to supply an existing copper deficiency. In adults, it is questionable whether any benefit is derived from the addition of copper to iron therapy.

Cobalt is another element which under certain conditions can stimulate erythrocyte and hemoglobin formation. This action is seen in the production of experimental polycythemia by cobalt, and also in the cure of certain nutritional anemias of sheep. In other species, however, cobalt has not been proved of value in the treatment of nutritional anemias. It has not been established that any other metals are essential for hemoglobin synthesis.

Iron therapy in the nutritional anemias of infancy presents problems which are fundamentally similar to those encountered in adult hypochromic anemias and discussed at our last conference. Again the clinical impression is that ferrous iron is more effective than ferric iron. The dose in infants seems to be roughly proportional to that recommended for adults, calculated on the basis of body weight, usually about 15 to 30 grains of ferric ammonium citrates or from 6 to 8 grains of ferrous sulfate daily by mouth. As in the iron deficiency anemias of adults, the administration of hydrochloric acid is without benefit, food iron is relatively ineffective, and the efficacy of iron therapy may be interfered with by various factors, especially infection. In infants the choice of an iron preparation is usually limited by the fact that a soluble salt must be used. Unanimity is lacking as to the exact indications for iron therapy in infants, but it is generally agreed that when hemoglobin values less than 10 Gm. per hundred cubic centimeters of blood is consistently obtained, iron is indicated. Copper deficiency is more likely to play a

role in the anemias of infants than of adults, and in rare instances iron-refractory anemias may be benefited by the addition of a minute amount of copper, 1 mg. a day, to the iron prescription.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT. HOWARD A. CARTER, Secretary.

HOLMSPRAY VAGINAL POWDER INSUFFLATOR ACCEPTABLE

Manufacturer: T. J. Holmes Company, Inc., Chartley, Mass.

The Holmspray Vaginal Powder Insufflator, No. 622, provides a means by which powders effective in the treatment of *Trichomonas vaginalis* and other organisms can be blown into the vaginal cavity. The device consists of a glass bottle to which is attached spray parts, a rubber shield and rubber bulb; the metal parts are chromium plated. The spray tube is interchangeable and is supplied in sizes for adults and infants.

The Council had the Holmspray Vaginal Powder Insufflator investigated and the report indicated that it insufflates the powder satisfactorily into the vagina. However, the rubber shield if placed close to the introitus interferes with the insufflation of the powder probably owing to the fact that it makes a closed circuit. It is, however, a satisfactory apparatus for blowing the powder into the vaginal lumen with a bivalve speculum in place.

The Council voted to accept the Holmspray Vaginal Insufflator, No. 622, for inclusion on its list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

CHORIONIC GONADOTROPIN (FOLLUTEIN)

The gonadotropic substance excreted in the urine of pregnant women is a water-soluble substance which has been prepared in a highly purified form. It is a glycoprotein containing about 12 per cent of galactose.

In rodents injection of pregnancy urine, or certain extracts thereof, induces follicular growth and corpus luteum formation. In man, the activity of pregnancy urine was first demonstrated in 1928. At that time, it was considered that the responsible substance was secreted by the anterior pituitary. At the time, the concept was advanced that this gonadotropin consisted of two hormones—prolan A, the follicle stimulating hormone, and prolan B, the luteinizing hormone—on the basis of its effect in the rat, mouse and rabbit. Further experimentation, however, has revealed that this substance is a single entity and not composed of two factors, that it arises from the placenta rather than from the pituitary, and that it differs fundamentally from the gonadotropins of the anterior lobe.

A significant physiologic difference between chorionic gonadotropin and preparations from the anterior pituitary is the inability of the former to stimulate to any appreciable extent the ovary of the monkey or the human being. Injection of chorionic gonadotropin into primates will not induce follicular growth or corpus luteum formation. On the contrary, reliable investigators have observed definite degenerative changes in the ovaries of women and monkeys treated with this substance. In addition, no clearcut endometrial responses have been observed in primates treated in this manner, which indicates conclusively the inability of this substance to stimulate the growth of normal ovarian structures.

The physiologic action of chorionic gonadotropin is not limited to the female, but it exerts a definite effect on the male reproductive organs. It is generally agreed that this substance acts on the interstitial cells of the testes, causing them to elaborate

Council on Foods

ACCEPTED FOODS

THE FOLLOWING ADDITIONAL FOODS HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO ACCEPTED FOODS.
FRANKLIN C. BING, Secretary.

FOODS FOR SPECIAL DIETETIC PURPOSES (See Accepted Foods, 1939, p. 315).

S & W Fine Foods, Inc., San Francisco.
NUTRADIENT BRAND WHOLE CARROTS, water packed, without added sugar or salt.

Analysis (submitted by manufacturer).—Moisture 87.0%, total solids 8.3%, ash 0.3%, fat (ether extract) 0.2%, protein (N \times 6.25) 0.5%, crude fiber 0.8%, carbohydrates other than crude fiber (by difference) 6.5%.
Calories.—0.30 per gram; 9 per ounce.

NUTRADIENT BRAND VALENCIA ORANGE JUICE UNSWEETENED.
Analysis (submitted by manufacturer).—Moisture 87.0%, total solids 13.0%, ash 0.4%, fat (ether extract) 0.1%, protein (N \times 6.25) 1.0%, reducing sugars as invert sugar 5.6%, sucrose (copper reduction method) 4.8%, crude fiber 0.1%, carbohydrates other than crude fiber (by difference) 11.4%, titratable acidity as citric acid 1.0%.
Calories.—0.51 per gram; 14 per ounce.

MILK AND MILK PRODUCTS OTHER THAN BUTTER (See Accepted Foods, 1939, p. 230).

Fort Dodge Creamery Company, Fort Dodge, Iowa.
GREEN GABLE BRAND EVAPORATED MILK.
Analysis (submitted by manufacturer).—Moisture 74.1%, total solids 25.9%, fat 7.9%, milk solids not fat 18.0%, ash 1.5%, protein (N \times 6.38) 6.7%, lactose 9.0%, carbohydrate (by difference) 9.8%.
Calories.—1.3 per gram; 36.9 per avoirdupois ounce.

The Borden Company, New York.
BORDEN'S EAGLE BRAND SWEETENED CONDENSED MILK.
Analysis (submitted by manufacturer).—Moisture 27.5%, total solids 72.5%, ash 1.9%, fat (ether extract) 9.1%, protein (N \times 6.38) 8.1%, sucrose 42.0%, milk solids 30.5%, non-fat milk solids 21.5%, carbohydrates (by difference) 54.4%.
Calories.—3.27 per gram; 93 per ounce.

PREPARATIONS USED IN THE FEEDING OF INFANTS (See Accepted Foods, 1939, p. 156).

Libby, McNeill & Libby, Chicago.
LIBBY'S BRAND HOMOGENIZED BABY FOODS FORMULATED COMBINATION No. 7, vegetable soup containing celery, potatoes, peas, carrots, tomato juice, soya bean flour and barley flour with a small amount of added sodium chloride.

Analysis (submitted by manufacturer).—Moisture 5.2%, total solids 14.8%, ash 1.3%, sodium chloride 0.2%, fat (ether extract) 0.02%, protein (N \times 6.25) 4.0%, crude fiber 0.4%, carbohydrates other than crude fiber (by difference) 9.1%, calcium (Ca) 0.032%, phosphorus (P) 0.075%, iron (Fe) 0.0014%, copper (Cu) 0.00028%.
Report of titration test (1939) indicates that this product contains 0.023 mg. of ascorbic acid per gram, 0.64 per ounce. Protocols of biologic assay (1939) indicate that this product contains approximately 22.5 U. S. P. units of vitamin A per gram, 639 per ounce; and 0.33 Sherman-Rat growth tests have demonstrated the presence of small amounts of vitamin B₁ (thiamine).
Calories.—0.53 per gram; 15.1 per ounce.

SUGARS AND SYRUPS (See Accepted Foods, 1939, p. 327).

Penick & Ford, Ltd., Incorporated, New York.
PENICK BRAND IMITATION MAPLE WAFFLE SYRUP, a mixture of corn syrup and sugar syrup with imitation maple flavor.
Analysis (submitted by manufacturer).—Moisture 25.3%, total solids 74.7%, ash 0.2%, nitrogen 0.003%, sucrose 26.0%, reducing sugars as dextrose (before inversion) 28.8%, carbohydrates other than crude fiber (by difference) 74.5%.
Calories.—2.98 per gram; 85 per ounce.

The Pure-Grape Sugar Manufacturing Co., Ltd., Athens, Greece, product distributed in the United States by Aegean Trading Company, New York.
GRAPE SUGAR (DEXTRUSE), a carbohydrate for use as a sweetening in the preparation of other foods, made from fresh grapes or raisins.
Analysis (submitted by manufacturer).—Moisture 10.1%; ash 0.4%; sugar as glucose (Munson-Walker) 89.7%; polarization 10% solution at 25 C., 9.3 degrees angular; specific rotation at 25 C., 46.5 degrees; soluble starch, chlorides and sulfates, none; arsenic and heavy metals, none; sulfite, trace.
Calories.—About 3.6 per gram; 102 per ounce, depending on the amount of water present.

the androgenic hormone of the testis, which in turn induces growth of the accessory sex organs. This substance is effective in male monkeys and human beings. Among the reactions induced in the monkey is the descent of the testes in the puberal animal. In some animals there may be some increase in the size of the seminiferous tubules, but there is little if any effect on the germinal epithelium. Spermatogenesis is, however, maintained by chorionic gonadotropin in recently hypophysectomized rats, but it is not restored after atrophy or induced in normal immature rats.

The therapeutic application of chorionic gonadotropin has covered a wide range of conditions. Many of the trials have been on an unsound or improperly conceived basis. Its use in the treatment of ovarian disturbance, for example, has no scientific rationale at the present time, although when it was first introduced for the treatment of these dysfunctions the physiologic basis for therapy appeared excellent.

CHORIONIC GONADOTROPIN (FOLLUTEIN).—

The water-soluble gonadotropic substance obtained from the urine of pregnant women. This preparation is standardized in international units. One international unit equals 0.1 milligram of a standardized powder (see Council Report, J. A. M. A. 113:2418 [Dec. 30] 1939).

Actions and Uses.—Its use is recommended in the treatment of cryptorchidism where there are no anatomic lesions causing obstruction of the testicular descent. The diagnosis of an anatomic lesion can often be made in this manner where this therapy instituted at an early age when it is found that gonadotropin cannot induce descent. Injections should not be prolonged after six to eight weeks if no descent is obtained, since excessive therapy may result in undesirable responses of precocious puberty and possibly other harmful reactions.

The diagnosis of cryptorchidism should not include those cases which have been termed pseudocryptorchids, in which the testes are maintained in the inguinal canal as the result of reflex muscular spasm. It will be found that the testes return to the normal scrotal position on gentle handling and warmth.

Chorionic gonadotropin therapy in other disorders is still considered experimental because of the lack of sufficient published data. This treatment of hypogonadism in the adult is considered experimental at the present time. Its value in the treatment of uterine bleeding of functional nature is also as yet unproved, although numerous reports on this therapy have appeared in scientific publications. There is less enthusiasm for this therapy at the present time than there was several years ago. Considerable disagreement exists among the various investigators regarding the type of bleeding benefited by chorionic gonadotropin therapy.

Dosage.—The usual dose in treating cryptorchidism is from 200 to 500 international units two to three times a week. Long-continued injections may be dangerous and treatment should not be maintained after eight weeks in the absence of progressive descent. Therapy should be discontinued on the development of signs of precocious maturity.

Follutein-Squibb.—A nonproprietary brand of chorionic gonadotropin (follutein)-N. N. R. Both follutein and chorionic gonadotropin are nonproprietary terms.

Manufactured by E. R. Squibb & Sons, New Brunswick, N. J., by license under U. S. patent 1,910,298. E. R. Squibb & Sons agree to withdraw their rights to Follutein as a proprietary name.
Follutein-Squibb, 500 International Units: A glycerin solution of chorionic gonadotropin (follutein)-N. N. R. which, when diluted with the 4 cc. of sterile distilled water in the accompanying vial, provides a solution having a potency of 100 international units per cubic centimeter.
Follutein-Squibb, 1,000 International Units: A glycerin solution of chorionic gonadotropin (follutein)-N. N. R. which, when diluted with the 8 cc. of sterile distilled water in the accompanying vial, provides a solution having a potency of 100 international units per cubic centimeter.
Follutein-Squibb, 5,000 International Units: A glycerin solution of chorionic gonadotropin (follutein)-N. N. R. which, when diluted with the 8 cc. of sterile distilled water in the accompanying vial, provides a solution having a potency of 500 international units per cubic centimeter.
Follutein is prepared from the urine of normal pregnant women by precipitating the active principle from the urine by addition of ethyl alcohol to give a concentration of more than 85 per cent alcohol, extracting the hormone from the precipitate with dilute alkaline water, and then salting out the active principle from this solution with ammonium sulfate. Further purification is made by fractionating in 50 per cent alcohol at the isoelectric point of impurities, which are removed by centrifuging. The active principle is obtained by raising the alcohol concentration to 85 per cent. The precipitate is removed by filtration and dried. This precipitate is dissolved in 90 per cent glycerin, precipitating the active principle from the urine by addition of ethyl alcohol to give a concentration of more than 85 per cent alcohol, extracting the hormone from the precipitate with dilute alkaline water, and then salting out the active principle from this solution with ammonium sulfate. Further purification is made by fractionating in 50 per cent alcohol at the isoelectric point of impurities, which are removed by centrifuging. The active principle is obtained by raising the alcohol concentration to 85 per cent. The precipitate is removed by filtration and dried. This precipitate is dissolved in 90 per cent glycerin, compared in this procedure to the International Standard powder. The product is then diluted until its biologic activity is equal to that of the international standard.

SATURDAY, JUNE 8, 1940

THE PLATFORM OF THE AMERICAN MEDICAL ASSOCIATION

The American Medical Association advocates:

1. The establishment of an agency of the federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy.
2. The allotment of such funds as the Congress may make available to any state in actual need, for the prevention of disease, the promotion of health and the care of the sick on proof of such need.
3. The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility.
4. The development of a mechanism for meeting the needs of expansion of preventive medical services with local determination of needs and local control of administration.
5. The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration.
6. In the extension of medical services to all the people, the utmost utilization of qualified medical and hospital facilities already established.
7. The continued development of the private practice of medicine, subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability.
8. Expansion of public health and medical services consistent with the American system of democracy.

SUPREME COURT DECIDES FOR TRIAL ON INDICTMENT OF AMERICAN MEDICAL ASSOCIATION AND OTHERS UNDER SHERMAN ANTI-TRUST ACT

On Dec. 20, 1938, an indictment was filed in the District Court of the United States for the District of Columbia charging the American Medical Association, Medical Society of the District of Columbia, Harris County (Texas) Medical Society, Washington Academy of Surgery and twenty-one individual defendants with conspiracy to violate section 3 of the Sherman Anti-Trust Act. The defendants filed a demurrer to the indictment. This means that the defendants contended that, even assuming everything alleged in the indictment to be true, there was no violation of the law as charged. Of course, on the issue thus formed the courts were bound to take as true, whether or not it was in fact true, each and every

allegation of the indictment. The District Court agreed with the defendants' contention and on July 26, 1939, sustained the demurrer and dismissed the indictment.¹

From that order Thurman Arnold, as Assistant Attorney General, prosecuted an appeal to the Court of Appeals of the District of Columbia. While the case was pending in the Court of Appeals, and before a decision there, the government filed a petition in the Supreme Court of the United States for a writ of certiorari to remove the case from the Court of Appeals to the Supreme Court of the United States. The defendants did not oppose this petition, but the Supreme Court denied it,² probably on the theory that the issues presented were raised by demurrer and that the case had not been tried and the real facts did not appear in the record.

Thereafter the Court of Appeals proceeded to consider the case and on March 4, 1940, it reversed the order of the District Court and remanded the case to the District Court for trial.³ The Court of Appeals in its opinion said:

Defendants say that what they are charged with doing amounts to no more than the regulation of membership in the society and the selection of the persons with whom they wish to associate; that under their rules disobedient members may lawfully be disciplined, and that discipline does not amount to unreasonable restraint. This may very well be true, and in considering the contention we are not unmindful of the importance of rules of conduct in medical practice, rules which can best be made by the profession itself. We recognize, in common with an almost universal public opinion, that in the last half century, through this means, the quack and the charlatan have been largely deprived of the opportunity of preying on the unfortunate and the credulous. We also recognize that in personal conduct and in professional skill the rules and canons, so established, have aided in raising the standards of medical practice to the advantage of the whole country. We are mindful of a generally known fact that under these rules and standards there has developed an esprit de corps largely as a result of which the members of the profession contribute a considerable portion of their time to the relief of the unfortunate and the destitute. All of which may well be acknowledged to their credit.

The court went on to say that, notwithstanding the foregoing, the defendants ought not restrain trade and that it thought under the allegations of the indictment the true facts should be brought out by a trial of the case, and that on a trial, if in fact restraint was shown, it would not necessarily violate the law if such a restraint was reasonable as a regulation of professional practice and that whether or not such restraint was reasonable as a regulation of professional practice must be shown in evidence on the trial of the case.

On April 29, 1940, the defendants filed in the Supreme Court of the United States their petition for a writ of certiorari to review the decision of the said Court of Appeals. The government opposed this petition and argued that the Supreme Court of the United States ought not decide the issues in this case on a

1. 28 Fed. Sup. 752.
2. 84 L. Ed. (Adv.) 96.
3. 110 Fed. (2d) 703.

demurrer to the indictment but ought to wait until the case had been tried and the real facts appear of record.

The Supreme Court apparently agreed with the government's contention in this regard, because on June 3 it denied the defendants' petition for a writ of certiorari. The Supreme Court of the United States did not decide the legal issues or any of them against the defendants but merely refused to review the decision of the Court of Appeals at this time and in effect said that the defendants would have to stand trial before it would pass on the issues.

The American Medical Association, its officers and the other defendants in this case feel certain that they have not violated the Sherman Anti-Trust Act and feel certain that they will be vindicated on a trial of this case, but they regret the expense that will necessarily be incurred in such a trial.

HOSPITAL CONSTRUCTION BILL PASSES SENATE

Without a dissenting voice the Wagner-George bill for the construction of hospital facilities, health, diagnostic and treatment centers, and facilities relating thereto passed the Senate, May 30. Two amendments to the bill, as reported by the Committee on Education and Labor, were proposed from the floor of the Senate; both were unanimously adopted. Senator Barbour of New Jersey sponsored an amendment to assure that facilities to be constructed under the bill will be made available without discrimination on account of race, creed or color. This amendment provides that, where separate health facilities are required by law for separate population groups, equitable provisions on the basis of need will be made for facilities and services of like quality for each such group. The other amendment, sponsored by Senator Murray of Montana and adopted without opposition, provides that the eight appointed members of the National Advisory Hospital Council shall be selected not only from leading medical or scientific authorities but also from osteopathic authorities who are outstanding in matters pertaining to hospitals and other public services. No doubt Surgeon General Parran, who may have the responsibility of nomination of members of the proposed hospital council, will have some difficulty in finding an osteopath who is "outstanding in matters pertaining to hospitals and other public services."

The bill now goes to the House of Representatives, where it will receive consideration by the Committee on Interstate and Foreign Commerce. The bill should be modified so that the definition of the term "hospital" covers institutions primarily for the care of the sick rather than health, diagnostic and treatment centers. It should be amended to eliminate the meaningless reference to "outstanding" osteopathic authorities. It should be amended to give the Advisory Council a positive voice in the construction program not only for the first

year but also during the last five of the six years that the bill will be in operation. It should be amended to provide for the selection of the members of this council by the Chief Executive.

This proposal is an experimental venture; it would be most unfortunate if the inclusion of unwise provisions prevented a sound appraisal of its fundamental merits.

A NEW MANUAL FOR HEALTH EXAMINATIONS

A committee appointed by the Board of Trustees to cooperate with the Bureau of Health Education in revising the *Manual for Periodic Health Examinations of Apparently Healthy Persons* has completed its work and has issued a revision under the title *Periodic Health Examination: A Manual for Physicians*.¹ The new manual represents a complete revision of the material which was first issued in 1925 and superficially revised in 1932. The committee endeavored to consider some of the reasons why the periodic health examination of apparently normal persons had not been more widely accepted as a habitual practice even among intelligent and well educated persons. There were two reasons, the committee concluded, for the situation: (1) excessive and unjustifiable claims for what periodic health examinations can be expected to accomplish and (2) a feeling on the part of the public, whether justified or not, that periodic health examinations, though theoretically desirable, are excessively expensive.

In the preface to the 1940 edition, the committee takes cognizance of these barriers to progress and indicates definite limitations in the claims to be made on behalf of periodic health examinations: "No promise or prophecy of good health in the future should be offered. The only honest or valid claims are that it serves to measure the present health status of the individual, subject to the qualification that obscure or insidious disease may not always be discoverable by methods at present available. Further, the examination discloses habits of living and environmental factors which may be unhealthful but susceptible of correction. Finally, of course, it gives opportunity for treatment of early or preclinical stages of disease." The committee also, for the first time, advances a new conception of the periodic health examination, consisting of a basic examination of the patient including health, history, medical examination and only chemical and microscopic urinalysis, hemoglobin determination and stained blood smear and blood test for syphilis as routine laboratory procedures. The committee suggests that "additional laboratory procedures such as gastric analysis, blood cell and differential counts, basal metabolic rate determination, blood chemistry, x-ray examinations, functional tests and consultations with specialists be considered as

1. *Periodic Health Examination: A Manual for Physicians*, Bureau of Health Education, Chicago, American Medical Association. Single copies 25 cents.

accessory methods to be used only where the basic examination indicates their necessity" and that "when- ever the patient is unable to afford the accessory examinations and these are not available at public expense, the physician should nevertheless proceed to advise the patient to the best of his ability under the circumstances."

In most respects there can be little disagreement with the recommendations made, although not all will concur in the statement that the taking and recording of blood pressure measurements constitute a portion of the physical examination record which can be satisfactorily obtained by a "lay assistant, office clerk or nurse with accuracy."

Complete instructions are included in the manual for all the necessary physical examinations and many suggestions are given for hygienic advice to the patient. New features not found in previous editions of the manual include a suggested order of examination which correlates items on the physical examination blank with corresponding paragraphs in the manual of instructions. Except for the introduction, all paragraphs in the manual are numbered for ready reference to this suggested order of examination. Diagrams for posture diagnosis are included, the principal industrial hazards are enumerated, chief diseases and defects needing treatment are tabulated and there is a fairly complete discussion of general principles in prescribing diets, including some sample menus with computation of protein, fat and carbohydrate contents, unit values of vitamins A, B₁, C and G, and caloric values. There is a table of 100 calory portions of common foodstuffs and many other practical suggestions useful to the physician. The manual is intensively indexed.

There has been a coincidental revision of the record blank for periodic health examination necessitated by the fundamental changes in the manual.

The revised concept of a basic and relatively inexpensive health examination, plus the use of more extensive laboratory investigations only when specially indicated, should make a new appeal both to physicians and to the public. Greater growth in the popularity of the periodic health examination is desirable, since it has a definite if limited place in any program of individual health maintenance. Moreover, it opens wide possibilities to the physician as a health counselor and adviser.

Appreciation is due the committee² and the individual and organizational consultants³ who cooperated with the Bureau of Health Education in the preparation of the manual.

2. The members of the committee are Drs. Fremont A. Chandler, George H. Coleman, W. C. Danforth, Haven Emerson, Parker Heath, Leland S. McKittrick, Gordon B. New, William A. O'Brien, C. D. Selby, Paul D. White, and W. W. Bauer, chairman.

3. Walter C. Alvarez, M.D., Ruth Cowan Clouse, Ph.D., Robert L. Dickinson, M.D., Harold S. Diehl, M.D., Otto H. Foerster, M.D., Donald A. Laird, Ph.D., R. G. Leland, M.D., Lon W. Morrey, D.D.S., Carl M. Peterson, M.D., Paul A. Teschner, M.D., S. Bernard Wortis, M.D., American Heart Association, American Society for the Control of Cancer, American Society for the Hard of Hearing, National Committee for Mental Hygiene, National Society for the Prevention of Blindness and National Tuberculosis Association.

TULAREMIA

Since Francis¹ in 1919 recognized the identity of "deer fly fever" with the "plaguelike" disease of rodents which had been described by McCoy² several years earlier, the presence of human cases of this disease has been disclosed in forty-eight states and in the District of Columbia, as well as in a number of foreign countries. The symptoms, diagnosis and pathology of this disease, named tularemia by Francis and often called "rabbit fever," were extensively described a number of years ago in *THE JOURNAL*.³ Now attention is called to the increasing number of human cases and deaths from tularemia. A recent report⁴ devoted to a discussion of the sources, symptoms and prevention of tularemia states that there were 2,088 cases and 139 deaths from this disease in the United States alone in 1938. Moreover, complete returns will probably show that the death toll of the disease in 1938 was exceeded in 1939, since in the latter year 2,200 cases were reported.

While it is true that more than 90 per cent of the human cases of tularemia are due to contact with infected wild rabbits, it may also be noted that at the present time twenty-four types of American wild life have been implicated in transmitting the causative agent, *Bacterium tularense*, to man. Infections have resulted, for instance, from the bite of insects, such as the wood tick, dog tick and horsefly, as well as from the bites of animals such as the skunk, raccoon, coyote, tree squirrel, ground squirrel, opossum, dog and lamb. Since the vast majority of human cases result from contact with wild rabbits, however, those persons who are particularly exposed to infection are market men, hunters, housewives and others who handle and dress these animals. In these cases infection may be caused by pricking the skin with a piece of broken bone, by cutting with the skinning knife or by allowing infected body fluid, such as blood, to get into an abrasion of the skin. Even the pelts of infected animals may convey the infection.

Most patients recover from tularemia without permanent ill effects and thereafter enjoy immunity from the disease. Nevertheless about 5 per cent of the patients die, often after developing pneumonia. Despite reports in the literature of the favorable therapeutic effect of antiserum, it is now reported that there is no specific preventive or curative treatment for the disease.⁴ Those who are exposed to tularemia must take especial precautions to prevent infection. The use of rubber gloves by those who handle animals which may be infected has been suggested. Extreme care should be taken to avoid cutting or pricking the hands, and any possibly infected material which gets on the hands should be thoroughly washed off with soap and water and the

2. McCoy, G. W.: *Bull.* 43, U. S. P. H. & M. H. S., April 1911.

3. Francis, Edward: *Symptoms, Diagnosis and Pathology of Tularemia*. *J. A. M. A.* 91:1155 (Oct. 20) 1928.

4. Tularemia (Rabbit Fever), *Pub. Health Rep.* 55:667 (April 15) 1940.

hands should be disinfected. Since the disease may also be contracted by the consumption of infected meat that is insufficiently cooked, it is advisable to cook thoroughly any possibly infected meat. The need for stressing these preventive measures is obvious, since the reported increase in the number of human cases and deaths from tularemia indicates that many people who are exposed to infection are unaware of the danger.

Current Comment

THE NEW YORK TIMES SINGS A NEW TUNE

In the *New York Times* for Sunday, June 2, under the editorial column called Topics of the Times, appears the following statement: "Hitherto we have been stressing the health of the underprivileged. Now is the time to recall that health conditions in the lower one third of the nation have made notable gains in our generation. Our discontent has been impatience with what we considered insufficient progress. The fact of progress no one could specifically deny. The health of the Negro people in the crowded districts lags far behind conditions among the white population. But the health of the Negro people today is far better than it was a generation ago. Today, and for the duration of the emergency, it is the improvement already made and not the gap still to be covered that should be chiefly stressed." Apparently the *Times* has discovered that the welfare of a part of the nation is dependent on the welfare of the whole, and that the security of one third is dependent on the security of three thirds. Perhaps the new point of view will lead its editors to the reflection that progress in the care of the sick is not to be made by breaking down confidence of the people in the medical profession, which is the only body in the country legally, scientifically and by experience qualified to care for the sick.

"IN DEFENSE OF THE INDIVIDUAL"

In the *Atlantic Monthly* for June, Mr. Albert Jay Nock presents a stimulating essay with the title of this comment. In general his essay is an attack on collectivism and a review of the insidious manner of its approach to the American way of living. Mr. Nock particularly recommends "Democracy vs. Socialism," a work by Max Hirsch, which he says presents the "complete case against every known form and shade of State collectivism, from Marxism and Fascism down to the New Deal, leaving not a shred of respectability, or even of plausibility, to the claims of many of them." He continues, "Out of the mouths of the collectivists themselves it shows that the State does not and cannot administer a collectivist economy without bringing on consequences so calamitous as to end in a complete rebarbarization of society." The occurrences in recent years in Russia and in Germany should be sufficient to prove the truth of this latter statement. Mr. Nock points out that state collectivism made its way in England step by step, where it was to be brought in by "the progressive legalization of one bit of its pro-

gram after another, thus steadily widening the scope of State control." Indeed he feels that state collectivism is as fully dominant in England as it is in the systems which frankly call themselves totalitarian and that its dictates are enforced by the same means as those systems employ. The United States has approached state collectivism step by step. Mr. Nock feels that the character of the people of the United States is such as to be more easy of approach to such a system than other countries because it has been our tendency always to go to the state with any difficulties which would take time or be bothersome for us to settle for ourselves. He continues: "Some people are out of work—let the State make jobs for them. Some are hungry—let the State feed them. Some monopolies are oppressive—let the State break them up. There is a shortage of houses—let the State build more. Some have too much money—let the State take it away from them and redistribute it." To this we might add "There are some inadequacies and inefficiencies in parts of medical service—let the State take over all of medical service." Particularly hazardous is the concept that the difficulty with various forms of collectivism is not in collectivism itself but in the method of its administration. Thus one gets the notion that collectivism might work in Russia or in Germany if one could replace the present leaders with others, that collectivism might work better in this country under the administration of one party than it does under another. What Americans must remember is the basic thought that democracy depends on the principle of individual responsibility, and it is the breakdown of this principle that destroys democracy!

DIGITALIS FOR OBESITY

Too much publicity has apparently been given to the reports of a method of weight reduction which involves administration of digitalis for suppressing the appetite. The underlying thesis that the food intake determines the weight is, of course, correct; definite suppression of appetite will ordinarily be followed by loss of weight. Moreover the use of ipecac and similar drugs may result in a loss of appetite even before nausea and vomiting are manifested. Whether or not digitalis can produce a loss of appetite without harmful effects is more debatable. The work of Hatcher and Weiss in particular has shown that the nausea produced by digitalis is a reflex the sensory organ for which does not appear to be located in the heart. Thus the type of nausea which digitalis produces is at least partly due to factors other than gastric irritation. Indeed, nausea and vomiting are toxic symptoms of digitalis and constitute a warning to decrease or stop the administration of the drug. The observations reported by Bram¹ on this method of reducing body weight have attracted the attention of some writers for the public. Confirmatory evidence for his views is lacking. The method cannot be generally recommended unless its efficacy and safety have been thoroughly demonstrated by carefully controlled observations. At present the use of this technic is clearly in the experimental stage and uncontrolled use should be discouraged.

1. Bram, Israel: *M. Rec.* 151: 131 (Feb. 21) 1940.

THE NEW YORK SESSION

Open House at Merck & Co.

Physicians attending the annual session of the American Medical Association in New York are cordially invited to attend the Merck "open house" at Rahway, N. J., Friday afternoon, June 14, from 1:30 to 5:30 o'clock. Transportation will be provided. For additional details and cards of admission, physicians are asked to call at the Merck Exhibit, booth 280, Grand Central Palace.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—S. 3230, the Wagner-George Hospital Construction Act of 1940, has passed the Senate and, in the House, has been referred to the Committee on Interstate and Foreign Commerce. Senator Murray of Montana sponsored an amendment to the bill from the floor of the Senate proposing osteopathic representation on the National Advisory Hospital Council. The amendment was unanimously adopted. S. J. Res. 256 has passed the Senate, designating June 22 in each year as Doctor's Day. In the House this joint resolution has been referred to the Committee on the Judiciary. S. 1964 has been reported to the House, proposing to authorize national banking associations to contribute to community funds or to charitable, philanthropic or benevolent instrumentalities conducive to public welfare. S. 1460 has passed the Senate, providing uniform reciprocal hospitalization in any Army or Navy Hospital for retired personnel of the Army, Navy, Marine Corps and Coast Guard and Fleet Naval and Fleet Marine Corps. S. 3131 has passed the Senate, extending the benefits of the United States Employees' Compensation Act to members of the Officers' Reserve Corps and of the Enlisted Reserve Corps of the Army who were physically injured in line of duty while performing active duty or engaged in authorized training between dates of Feb. 28, 1925, and July 15, 1939, both inclusive. S. 3266 has passed the Senate, providing pensions, compensation, retirement pay and hospital benefits for certain Air Corps Reserve officers who were disabled while on active duty with the Regular Army. S. 3607, authorizing research by the United States Public Health Service with respect to the cause, diagnosis and treatment of dental diseases, was reached on the

Senate calendar May 28, but consideration of the bill was prevented by an objection lodged by Senator Gerry of Rhode Island. S. 3617 has passed the Senate, granting the consent and approval of Congress to an interstate compact relating to control and reduction of pollution in the Ohio River drainage basin. H. R. 9236 has passed the House and Senate, providing an additional appropriation of \$75,000 for the preparation of "talking books" for the blind.

Bills Introduced.—S. 3960, introduced by Senator Sheppard of Texas, proposes that the present grade of captain, Medical Administrative Corps, United States Army Reserve, be advanced to colonel, Medical Administrative Corps, United States Army Reserve. H. R. 9861, introduced by Representative Fish of New York, proposes to amend the act entitled "An Act to recognize the high public service rendered by Major Walter Reed and those associated with him in the discovery of the cause and means of transmission of yellow fever" by including therein the name of Dr. J. Wilson Poucher. H. R. 9889, introduced by Representative Whelchel of Georgia, proposes a federal appropriation of \$100,000 to erect a hospital at Jefferson, Ga., as a memorial to Dr. Crawford W. Long, "who was the first physician to perform an operation by use of ether, and for carrying on scientific research to further the study of surgery." The hospital, it is proposed, will be named "Crawford W. Long Memorial Hospital."

DISTRICT OF COLUMBIA

Change in Status.—S. 2013 has passed the Senate, proposing to amend the Code of the District of Columbia to provide for the organization and regulation of cooperative associations.

WOMAN'S AUXILIARY

Arkansas

The auxiliary to the Pulaski County Medical Society held a recent meeting in Little Rock with forty-one members attending. Miss Erle Chambers, executive secretary of the Arkansas Tuberculosis Association, spoke on the "Program of the Association in Arkansas."

Mrs. W. R. Brooksher Jr. was named general chairman of the Arrangements Committee of Women's Activities for the annual meeting of the auxiliary to the Arkansas Medical Society in Fort Smith, April 15-17. Members of the auxiliary to the Sebastian County Medical Society were hostesses to the ladies who attended the annual meeting.

Michigan

The auxiliary to the Bay County Medical Society met in Bay City recently with thirty-seven members in attendance. Miss Libby Kessler reviewed "Dr. Hudson's Secret Journal."

At a recent meeting of the auxiliary to the Saginaw County Medical Society members voted to contribute to the purchase of an iron lung for the hospital and to send *Hygieia* to twenty rural schools of the county.

The auxiliary to the Kalamazoo County Medical Society met at the Kalamazoo Academy of Medicine recently. Dr. Paul W. Harrison spoke on his experiences in Arabia.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

State Society Condemns Patents for Profit.—The Medical Association of the State of Alabama adopted a resolution, April 18, in which it condemns as unethical the patenting of drugs or medical appliances for profit whether the patent is held by a physician or is transferred by him to some university or medical research foundation. This action, according to the resolution, deprives the needy sick of the benefits of many new medical discoveries through the acts of medical men. Introduced by Dr. Marye Y. Dabney, Birmingham, the resolution points out that there is a growing tendency to patent drugs in the name of universities and foundations in connection with universities. The effect of the patents is to increase the price of the drugs because of the royalties imposed by the foundations, thus affecting the needy public who are prevented from buying them on account of the necessarily high prices asked.

CALIFORNIA

Society News.—The Los Angeles Society of Neurology and Psychiatry was addressed, April 17, among others, by Drs. Cullen Ward Irish and Karl O. Von Hagen on "Douglas's 'The Physical Mechanism of the Human Mind.'"—At a meeting of the Los Angeles Society of Ophthalmology and Otolaryngology, April 22, observing the thirty-fifth anniversary of its founding, the speakers included Drs. Etta C. Jeancon on "Cataract Operation in Tuberculosis"; Clinton A. Wilson, "Unexplained Optic Neuritis," and Helen E. Preston, "Congenital Iris Atrophy with Anterior Synechiae." A dinner was given to honor founders and past presidents of the society.—At the first and organization meeting of the Los Angeles County Physicians' Aid Association, April 3, the following officers were chosen: Drs. Elizabeth M. Hohl, president; Herbert O. Bames, vice president; Olga McNeile, secretary, and Alfred R. Robbins, treasurer. Its official address will be 671 North Mariposa Avenue, Los Angeles.

FLORIDA

New Society of Specialists.—The Florida Society of Ophthalmology and Otolaryngology was formed at a meeting in Tampa, April 29. Officers are Drs. Hermon Marshall Taylor, Jacksonville, president; Sherman B. Forbes, Tampa, vice president, and Carl E. Dunaway, Miami, secretary. During the annual meeting of the state medical association in 1939, ophthalmologists and otolaryngologists met informally with a view to a permanent organization, but final action was delayed until this year.

Short Graduate Course.—The Florida Medical Association will hold its annual graduate short course at the George Washington Hotel, Jacksonville, June 24-29. The instructors will be:

Dr. Raymond W. McNealy, associate professor of surgery, Northwestern University Medical School, Chicago.

Dr. William T. Pride, professor of obstetrics, University of Tennessee College of Medicine, Memphis.

Dr. Willis Campbell, professor of orthopedic surgery, University of Tennessee College of Medicine.

Dr. Henry M. Thomas Jr., associate professor of medicine, Johns Hopkins University School of Medicine, Baltimore.

Dr. Daniel C. Darrow, associate professor of pediatrics, Yale University School of Medicine, New Haven, Conn.

Dr. Stuart N. Michaux, professor of gynecology, Medical College of Virginia, Richmond.

Dr. Paul Padgett, Baltimore, will present the course in venereal diseases, which has been substituted for neuropsychiatry this year.

IDAHO

Society News.—The Pocatello Medical Society was addressed in Pocatello, April 4, by Drs. Richard P. Howard and Abram M. Newton, Pocatello, who presented a symposium on the medical and surgical treatment of peptic ulcer. At an earlier meeting of the society a symposium on sulfanilamide and related drugs, their indications, contraindications, dosage and mode of action was presented by Drs. Wilfred L. Olsen, Ben C. Eisenberg and Eugene V. Simison.

Professional Groups Protest Regimentation.—Physicians, dentists and pharmacists of south central Idaho recently took steps to form a committee that will serve as a working unit against measures which might bring governmental control of the professions, newspapers reported. The action was taken at a dinner meeting in Twin Falls. The speakers included Dr. Harry E. Rhodehamel, Spokane, Wash., northwestern representative of the National Physicians' Committee for Extension of Medical Service; Donald S. Whitehead, lieutenant-governor of Idaho and a pharmacist, and F. A. Kallusky, D.D.S., Buhl, president of the South Central Dental Society. Dr. Harry E. Lamb, Twin Falls, president of the Southside Medical Society, opened the meeting and J. J. Lynch, secretary of the state pharmaceutical group, was toastmaster at the dinner.

ILLINOIS

State Medical Election.—Dr. Charles H. Phifer, Chicago, was chosen president-elect of the Illinois State Medical Society at its annual meeting in Peoria, May 23, and Dr. James S. Templeton, Pinckneyville, was installed as president. Other officers are Drs. Arthur Sprenger, Peoria, and James H. Finch, Champaign, vice presidents; A. J. Markley, Belvidere, treasurer, and Harold M. Camp, Monmouth, secretary. The 1941 meeting will be held in Chicago.

Chicago

The Luckhardt Lecture.—The seventh annual Arno B. Luckhardt Lecture of Delta chapter of Phi Beta Pi medical schools of the University of Chicago was delivered by Dr. Andrew C. Ivy, Nathan Smith Davis professor of physiology and professor of pharmacology, Northwestern University Medical School, April 19. His subject was "The Gastro-Intestinal Hormones: An Illustration of the Influence of a Great Teacher."

Society News.—The Chicago Society of Allergy devoted its meeting, May 20, to a symposium on intrinsic asthma; the speakers were Drs. Edward G. Tatge, Evanston, Ill., Clarence Bernstein Jr., Morris A. Kaplan and Morris J. Hoffman.—The Chicago Society of Internal Medicine was addressed, May 27, among others, by Fred S. Grodins, Stafford L. Osborne and Dr. Andrew C. Ivy on "The Effect of Bile Salts on Hepatic Blood Flow." Dr. James G. Carr gave the presidential address on "The Physician and the Internist."—Drs. Hollis E. Potter, Chicago, and Bruce H. Douglas, Detroit, discussed "The Miniature X-Ray Film" before the Chicago Tuberculosis Society, May 16.

Dr. Harvey to Become Professor Emeritus.—Dr. Basil C. H. Harvey, professor of anatomy and dean of students, including medical students, Division of Biological Sciences, University of Chicago, will become professor emeritus September 1. Born in Watford, Ont., Canada, in 1875, Dr. Harvey graduated at the University of Toronto Faculty of Medicine in 1898. He practiced medicine in Watford until 1901, when he joined the faculty of the University of Chicago as assistant in anatomy, and was made full professor in 1917. In 1923 he was named dean of medical students and in 1931 his deanship was extended to include all students in the newly created Division of Biological Sciences. Dr. Harvey was a major in the World War.

Lectures on Biochemistry.—A group of lectures on biochemistry divided into three series has been arranged by the department of biochemistry, University of Chicago, as a special feature of the first term of the summer quarter. The first group will be delivered June 25-27 by Dr. Cyril N. H. Long, Sterling professor of physiologic chemistry, Yale University School of Medicine, New Haven, Conn., on "Recent Studies on the Pancreas-Suprarenal-Pituitary Relations in Diabetes Mellitus." Edward A. Doisy, Ph.D., professor and director of the department of biochemistry, St. Louis University School of Medicine, St. Louis, will give the second series, July 9-10, on "The Vitamin K Problem." The last group will be on "Recent Advances in Enzyme Chemistry" with James Batcheller Sumner, Ph.D., professor of biochemistry, Cornell University Medical College, New York, as the speaker, July 15-17. Tickets may be obtained by writing to the director of the summer quarter, University of Chicago.

INDIANA

Society News.—The Greene County Medical Society was addressed in Linton, May 16, by Dr. Harold J. Pierce, Terre Haute, on "General Considerations of Carcinoma."—Dr. Otto L. Siewert, Logansport, discussed "The Eye in General Practice" before the Carroll County Medical Society in Camden, May 10.—Dr. William M. Doughty, Cincinnati, addressed the

Dearborn-Ohio County Medical Society in Lawrenceburg, May 2, on "Fractures of the Jaw."—The Parke-Vermillion Counties Medical Society was addressed in Clinton, May 15, by Dr. Alexander W. Cavins, Terre Haute, on "Myomas."—Dr. Ernest R. Carlo, Fort Wayne, discussed "Heart Disease in Children" before the Huntington County Medical Society, Huntington, May 7.

Serum Center to be Established.—The Indiana University School of Medicine, Indianapolis, has accepted funds from the Variety Club of Indianapolis to establish a convalescent serum center on the campus for the use of the medical center and physicians throughout the state. According to the state medical journal, the serum center will be the first to be established in Indiana on any extensive scale. At present Indiana physicians needing serums must send outside the state, the closest station being Chicago. Dr. Matthew Winters, professor and head of the department of pediatrics, has been appointed chairman of a committee to supervise the establishment of the center.

IOWA

Twin Lakes District Meeting.—The annual meeting of the Twin Lakes District Medical Society will be held at Rockwell City, June 20. The program has been designed for the general practitioner and speakers will include:

Dr. Nelson W. Barker, associate professor of medicine, University of Minnesota Graduate School, Minneapolis-Rochester, Minn.

Dr. Frederic W. Schlutz, chairman of the department of pediatrics, School of Medicine of the Division of Biological Sciences, University of Chicago.

Dr. Edward L. Cornell, assistant professor of obstetrics, Northwestern University Medical School, Chicago.

Dr. John S. Coulter, associate professor of physical therapy at Northwestern.

Dr. Frank R. Peterson, professor and head of the department of general surgery, State University of Iowa College of Medicine, Iowa City.

Dr. Ira H. Lockwood, Kansas City, will discuss "Medical Economics and the National Physicians Committee."

MAINE

Society News.—Dr. Herbert T. Kelly, Philadelphia, discussed "Important Phases of Nutrition and Vitamin Deficiency Disorders" before the Cumberland County Medical Society in Portland, April 25.—Dr. James M. Parker, Portland, addressed the Portland Medical Club, April 2, on "The Surgical Treatment of Varicose Veins."—The Kennebec County Medical Society was addressed in Augusta, April 18, by Dr. William Reid Morrison, Boston, on "Management of Complications of Appendicitis."—Dr. Joseph H. Pratt, Boston, addressed the Penobscot County Medical Association, April 16, on "Recent Advances in the Diagnosis and Treatment of Pancreatic Disease."—A symposium on the management of head injuries was conducted before the York County Medical Society in Kennebunk, April 3; the speakers included Drs. Harry Eugene Macdonald Jr. and Erastus E. Holt Jr., Portland; William V. Cox, Lewiston; John P. Goodrich, Waterville, and Harry Brinkman, Wilton.

MASSACHUSETTS

Kober Medal Awarded to Dr. Frederick Russell.—The George M. Kober Medal for 1940 was awarded to Dr. Frederick F. Russell, professor of preventive medicine and epidemiology, Harvard Medical School, Boston, at the annual meeting of the Association of American Physicians in Atlantic City, May 8. Dr. Russell, who served in both the Spanish-American and World wars, took charge of the yellow fever and malaria work of the Rockefeller Foundation in 1920. Since his resignation five years ago, Dr. Russell has been teaching. In 1941 Dr. William deB. MacNider, dean and Kenan resident professor of pharmacology, University of North Carolina School of Medicine, Chapel Hill, N. C., will be awarded the medal for his research on the liver and kidneys, it was announced.

Society News.—A symposium on adolescence was presented before the New England Pediatric Society in Boston and Brookline, May 15; the speakers were Drs. James S. Plant, Newark, N. J.; John Rock and Mr. C. E. Allen.—The New England Hospital Association will hold its 1941 meeting at the Hotel Statler, Boston, March 12-14.—The Pentucket Association of Physicians was addressed in Haverhill, May 9, by Dr. Robert E. Fleming, Boston, on "The Problem of Alcoholism in Its Relation to the Medical Profession" and Mr. Frank Stratton, Boston, "Analysis of Alcohol: Its Results and Relations to Conditions and Circumstances." Dr. Leroy M. S. Miner, Boston, will address the society, June 27, on "Contact Points of Two Professions." Dr. Miner is both a doctor of

medicine and a dentist.—The New England Roentgen Ray Society was addressed in Boston, April 26, among others, by Drs. George M. Wyatt and William E. Ladd on "Genito-Urinary Diagnosis and Treatment in Infants and Children: Persistent Pyuria, Kidney Embryoma and Retroperitoneal Neuroblastoma."—Dr. Charles H. Best, Toronto, discussed "Factors Influencing the Production and Liberation of Insulin from the Pancreas" before the Boylston Medical Society, Boston, May 13.

MICHIGAN

Vox Pop.—Dr. Linn M. Cudworth, Perry, was interviewed on the Vox Pop program recently over the Columbia Broadcasting System, following his selection as the typical American small town doctor. Dr. Cudworth was chosen from the physicians nominated by the letters of Vox Pop listeners. Born in Bainbridge, N. Y., Dr. Cudworth observed his seventeenth birthday February 23. All his forty-four years of practice, since his graduation at Baltimore University School of Medicine in 1896, have been spent in and around Perry. In the interview, Dr. Cudworth depicted generally the typical life of a small town doctor.

Society News.—Dr. Roby John F. Renshaw, Cleveland, discussed "Gastroscopy, Its Use in Diagnosis and Treatment" before the Wayne County Medical Society, Detroit, May 13. This was a joint session with the East Side Medical Society. Dr. Henry H. Kessler, Newark, N. J., discussed "Rehabilitation of the Industrially Disabled" before the former society, May 6.—Dr. Frederick A. Collier, Ann Arbor, addressed the Washtenaw County Medical Society, May 14, on "Some Surgical Diseases of the Colon and Rectum."—Drs. Herbert W. Harris and Martin Batts Jr., both of Ann Arbor, discussed infected compound fractures and bone tumors, respectively, before the Kalamazoo Academy of Medicine, May 21.—Dr. Edward R. Krumbiegel, Milwaukee, discussed "Pertinent Points in Diagnosis, Prophylaxis and Treatment of Contagious Diseases" before the Muskegon County Medical Society, May 17.—Dr. Clifford H. Keene, Ann Arbor, discussed "Management of the Cancer Patient" before the Genesee County Medical Society in Flint, April 24.

MINNESOTA

Awards for Research.—The John and Mary R. Markle Foundation has given \$3,600 to support studies of the significance of the excretion of various porphyrins by Dr. Cecil J. Watson, associate professor and director of the division of internal medicine, University of Minnesota Medical School. Dr. Arthur T. Henrici, professor of bacteriology and immunology, has received a grant of \$500 from the National Tuberculosis Association for an investigation of the acid-fast actinomycetes in relation to tuberculosis. Dr. Charles E. McLennan, instructor of obstetrics and gynecology, University of Minnesota Medical School, Minneapolis, has been awarded a fellowship by the Commonwealth Fund for a year's study with Dr. Eugene M. Landis, professor of internal medicine, University of Virginia Department of Medicine, Charlottesville, on problems concerning the toxemias of pregnancy.

Society News.—Dr. Erling W. Hansen, Minneapolis, was elected president of the Minnesota Academy of Ophthalmology at a meeting in Minneapolis, April 12; other officers include Drs. William A. Kennedy, St. Paul; Theodore R. Fritzsche, New Ulm, vice presidents, and George E. McGeary, Minneapolis, secretary-treasurer.—Dr. Raymond W. McNealy, Chicago, addressed the St. Paul Surgical Society, April 11, on "Perforation in Peptic Ulcer: A Critical Review in 700 Cases."—Among others, Dr. Russell R. Hendrickson, Wabasha, discussed "Diagnosis of Tuberculosis" before the ninth annual joint meeting of the Winona and Wabasha County Medical societies and the fifteenth annual dinner given by the Buena Vista Sanatorium Commission to the physicians of the counties, April 8, in Wabasha.—Dr. Orwood J. Campbell gave the president's address before the Minnesota Pathological Society, Minneapolis, May 21, on "Hyperinsulinism."

MONTANA

Personal.—Dr. Earl S. Porter, Lewistown, has been appointed a member of the state board of medical examiners for a term ending Feb. 10, 1947. He succeeds Dr. Arter W. Deal, Lewistown, who was not a candidate because of illness.—Dr. Ferdinand R. Schemm, Great Falls, addressed the Mount Powell Medical Society, April 15, on "The Management of Edema in Heart and Kidney Diseases."

State Medical Meeting in Bozeman.—The Montana State Medical Association will hold its annual meeting in Bozeman, June 19-20, under the presidency of Dr. Harold W. Gregg, Butte. The following members of the staff of the University of Minnesota Medical School, Minneapolis, will offer the scientific program:

- Dr. Nathaniel Logan Leven, (1) Problems in Biliary Tract Surgery, (2) Skin Transplantation.
- Dr. Walter A. Fansler, (1) Diagnosis and Treatment of Carcinoma of Bowel, (2) Office Treatment of Anorectal Disease.
- Dr. William A. O'Brien, (1) Cause and Prevention of Newborn and Premature Deaths, (2) Changes in Morbidity and Mortality Problems Incident to Aging of the Population.
- Dr. Cecil J. Watson, (1) Treatment of Heart Failure, (2) Jaundice Considered from the Standpoint of Diagnosis and Pathologic Physiology.
- Dr. Ernest M. Hammes, (1) Craniocerebral Injuries, (2) Modern Treatment of Psychiatric Disorders.

NEBRASKA

Courses in Obstetrics and Pediatrics.—The Nebraska State Medical Association and the division of maternal and child welfare of the state health department cooperated in presenting three weeks of courses in obstetrics and pediatrics in April. The lectures in obstetrics were given by Dr. Morris Edward Davis, associate professor of obstetrics and gynecology, the School of Medicine, Division of Biological Sciences, University of Chicago, and those in pediatrics by Dr. Moses Cooperstock, assistant professor of pediatrics and infectious diseases, University of Michigan Medical School, Ann Arbor. Two groups of towns were the centers for instruction: one including Columbus, Pender, Norfolk, O'Neill and Ainsworth; the other, Nebraska City, Beatrice, York, Hastings and Kearney.

NEW JERSEY

Personal.—Dr. Harold E. Longsdorf, Mount Holly, recently received a citizenship award for "meritorious service in the field of public health," presented by the Mount Holly Service Club.

Society News.—The Cape May County Medical Society held a joint meeting and banquet with the Cape May County Bar Association, April 11, with Dr. Edward G. J. Beardsley, Philadelphia, and Hon. Allen B. Endicott, Atlantic City, president of the state bar association, as guest speakers. A program on "Clinical Aspects of Pulmonary Disease" was presented before the Essex County Medical Society, Newark, April 11, by Drs. George G. Ornstein, James B. Amberson Jr., and Harry Wessler, New York, and William F. Rienhoff Jr., Baltimore. Dr. Perrin H. Long, Baltimore, addressed the Hudson County Medical Society, Jersey City, recently, on "Clinical Evaluation of the Therapeutic Effects of Sulfanilamide, Neoprontosil, Sulfapyridine and the Sulfathiazoles."

NEW YORK

Lectures on Physical Therapy.—The council committee on public health and education of the Medical Society of the State of New York sponsored a course of lectures in physical therapy for St. Lawrence County Medical Society, Ogdensburg, and the Jefferson County Medical Society, Watertown. The speakers were:

- Dr. Richard Kovacs, New York, The Therapeutics of Heat; Medical and Surgical Diathermy; Physical Therapy in Arthritis, April 18.
- Dr. William Bierman, New York, Therapeutic Use of Ultraviolet Radiation; Physical Therapy in Medical Conditions, April 25.
- Dr. Kovacs, Galvanic and Low Frequency Currents; Electrodiagnosis; Physical Therapy in Gynecology, May 2.
- Dr. Kristian G. Hansson, New York, Physical Therapy in Traumatic Conditions, May 16.

Foundation Established to Extend Psychotherapy to Patients of Moderate Means.—The Lake George Foundation, Inc., was established recently for the purpose of aiding in the extension of medical care and occupational therapy to patients of modest means suffering from maladjustments and psychosomatic disorders, it is announced. The foundation will work in close cooperation with Tratelja Farms, Diamond Point on Lake George, which was established in 1938 and will assist in the development of mental hygiene and child guidance clinics in the neighboring city of Glens Falls. Officers of the foundation are Mr. Henry E. H. Brereton, Diamond Point, president; Drs. John A. P. Millet, New York, and Daniel Blain, New Canaan, Conn., vice presidents; Mr. Laurence Millet, New York, secretary, and Mrs. Henry E. H. Brereton, Diamond Point, treasurer. Funds donated to the foundation will be administered by a board of trustees selected from persons prominent in civic affairs, social work and business administration both in the local community and in distant cities, according to the announcement.

New York City

Clinical Conference for Medicomilitary Officers.—The Metropolitan New York chapter and the New Jersey chapter of the Association of Military Surgeons of the United States will hold a clinical conference for medicomilitary officer personnel at the U. S. Marine Hospital, Stapleton, June 22. There will be general inspection and ward rounds and case presentations on miscellaneous subjects. All officers and prospective officers of the medical departments of the armed forces of the United States are invited to attend.

Reunion of Premature Babies at Exposition.—Plans have been announced for a reunion June 14 of the babies cared for at the 1939 New York fair in the station for incubator babies directed by Dr. Martin A. Couney. Forty-three babies will be brought by their parents. Each baby will be given a silver cup carrying its name and the insignia of the fair. A certificate signed by Dr. Couney and the president of the fair stating that the baby gained its start in life at the incubator station at the 1939 exposition will also be presented. Five babies in the original group of fifty died. Of the five who died, three arrived in a hopeless condition. Of the forty-five surviving babies, one representative of that government to Argentina, the father having been congenital hip disease and cannot be transported. There were thirty-six female babies in the original group and fourteen males. The average age was 9.5 days, ages ranging from 1 to 67 days. Of the seven weighing on admission under 1,000 Gm., five are now living and two are dead; of the twenty-five between 1,000 and 1,500 Gm., twenty-two are living and three dead; of the thirteen between 1,500 and 1,700 Gm. and the five between 1,700 and 2,000 Gm., all are living. An exhibit of *Hygeia* and its work in public education was a feature of the station last year and is installed again this year.

OHIO

Cleveland Health Agencies Plan Coordination of Efforts.—Public and private health agencies have recently formed an "Advisory Committee on Health and Hospitals in Greater Cleveland," headed by Mayor Harold H. Burton, James A. Reynolds, president of the board of county commissioners, and Dr. Robert H. Bishop Jr., director of University Hospitals, with Edward D. Lynde, executive secretary of the Welfare Federation of Cleveland, as secretary. Under this directing group the committee was subdivided into a committee on health and one on hospitals. The committee on health will make a study of health services and of the laws relating to them, recommend revisions that will end wasteful duplication, fix responsibility, simplify procedure and otherwise minimize the cost of and improve health service, and finally, develop a five year (or longer) program with special emphasis on disease prevention and health education. The committee on hospitals will do the same for hospitals, laying emphasis on the provision of adequate facilities in a community that makes more and more use of its hospitals. Dr. James A. Doull, professor of public health and hygiene at Western Reserve University School of Medicine, will be general consultant and ex officio member of both committees and Dr. Lyman F. Huffman, chairman of the public health committee of the Cleveland Academy of Medicine, will be ex officio member of both committees.

OREGON

Faculty Appointment.—Dr. William Y. Burton, St. Louis, has been appointed assistant professor of radiology at the University of Oregon Medical School, Portland, effective July 1. Dr. Burton graduated from Washington University School of Medicine, St. Louis, in 1936.

Internal Medicine Society Meeting.—The North Pacific Society of Internal Medicine met in Portland, April 13, with members of the faculty of the University of Oregon Medical School as guest speakers. They included Dr. Warren C. Hunter on the occurrence of thrombosis in the veins of the legs; Dr. Hance F. Haney, accelerator fibers in the vagus nerve; William B. Youmans, Ph.D., physiology of the small intestine; Wilbert R. Todd, Ph.D., biochemical studies in calcium metabolism, and Dr. Robert S. Dow, use of the oscillograph in neuro-anatomy.

Society News.—Drs. Thomas A. McKenzie and William B. Neal addressed the Lane County Medical Society, Eugene, April 19, on "Some Gastro-Intestinal Problems" and "Injection Treatment of Hernia" respectively. Dr. Lyle B. Kingery, Portland, addressed the Mid-Columbia Medical Society, Hood River, April 23, on "Superficial Mycotic Infection of the Skin." Dr. Howard P. Lewis, Portland,

addressed the Polk-Yamhill-Marion Counties Medical Society, Salem, April 9, on "Subacute Bacterial Endocarditis and Brucellosis."—At a meeting of the Umatilla County Medical Society, Pendleton, April 9, the guest speaker was Dr. James M. Odell, The Dalles, on "Differential Diagnosis in the Problem of Pulmonary Tuberculosis."

PENNSYLVANIA

Society News.—Drs. John S. Packard, Allenwood, and Esmond R. Long, Philadelphia, addressed the Lycoming County Medical Society, Williamsport, May 10, on "Diagnosis and Treatment of Tuberculous Tracheobronchitis," and "Tuberculin Test and X-Ray in Tuberculosis Case Finding" respectively.—Dr. Joshua Montgomery Deaver, Philadelphia, addressed the Lebanon County Medical Society, Lebanon, May 14, on "Surgical Management of Diseases of the Rectum and Colon."—Dr. Lawrence W. Smith, Philadelphia, addressed the Cambria County Medical Society, Johnstown, May 9, on "Refrigeration as an Adjunct to the Treatment of Cancer."

Philadelphia

Osler Memorial Building.—The Old Autopsy House at Philadelphia General Hospital has been restored and will be dedicated, June 8, as the Osler Memorial Building. The occasion will mark the premier showing of the painting "Osler at Old Blockley" by Dean Cornwell.

Pittsburgh

Emmerling Lecture.—Dr. Tinsley R. Harrison, associate professor of medicine, Vanderbilt University School of Medicine, Nashville, Tenn., delivered the Drs. Charles and Karl Emmerling Memorial Lecture at the headquarters of the Pittsburgh Academy of Medicine, May 13. His subject was "Newer Phases of Management of Hypertension."

VIRGINIA

New Hospital Buildings.—Dedication of new buildings for the Lynchburg General Hospital was held May 21. The Hon. Clifton A. Woodrum, Roanoke, Congressman from the sixth district, made an address in the afternoon and in the evening Dr. Wilburt C. Davison, dean of Duke University School of Medicine, Durham, N. C., delivered an address on "Opportunities in the Practice of Medicine."

Postgraduate Course on Internal Medicine.—The department of internal medicine of the University of Virginia School of Medicine, Charlottesville, will conduct a postgraduate course on recent advances in internal medicine, June 17-22, under the auspices of the department of clinical and medical education of the Medical Society of Virginia. Members of the faculty will be the instructors.

WASHINGTON

New Health Officers.—Dr. Cecil R. Fargher, Wenatchee, recently health officer of Chelan County, has been appointed health officer of Clark County, succeeding Dr. John A. Kahl, Vancouver. Dr. George R. Kingston, Walla Walla, recently health officer in Walla Walla County, has been appointed in Chelan County and Dr. Harold M. U'Ren, Spokane, succeeded him in Walla Walla. Dr. William A. Johnson, formerly of Tacoma, has been appointed in Cowlitz County.

Society News.—Dr. Max Pinner, New York, addressed the King County Medical Society, Seattle, April 22, on "The Practitioner's Role in Tuberculosis Work" and Dr. Harold E. Nichols, Seattle, reported on the work of the Anti-Tuberculosis League of King County. Dr. Alfred A. Strauss, Chicago, was the speaker, May 6, on "Ileostomy and Its Use in Surgery of the Colon."—Dr. Verne C. Hunt, Los Angeles, was the guest speaker at an all day meeting of the Spokane Surgical Society, April 27, presenting several papers and discussions.

WISCONSIN

Women's Field Army Honors Dr. Sleyster.—The Wisconsin unit of the Women's Field Army of the American Society for the Control of Cancer sponsored a dinner in honor of Dr. Rock Sleyster, Wauwatosa, President of the American Medical Association, April 19, at the Hotel Schroeder, Milwaukee. Dr. Frank L. Rector, Evanston, Ill., representative of the American Society for the Control of Cancer, was the principal speaker on "Why Women Fight Cancer." Other speakers were Drs. Raymond G. Arveson, Frederic, president of the State Medical Society of Wisconsin, and Charles Fidler, Milwaukee.

GENERAL

Society News.—The American College of Radiology will hold its annual meeting at the Commodore Hotel, New York, June 12, with Dr. Irvin Abell, Louisville, Ky., as the principal speaker. The business session will be followed by a banquet and an address by Dr. Frederick M. Hodges, Richmond, Va.—The Associated State Postgraduate Committees will hold its fourth annual meeting at the Shelton Hotel, New York, June 12.

Meeting of Food Technologists.—The first meeting of the Institute of Food Technologists will be held at the Morrison Hotel, Chicago, June 17-19. The program will offer symposiums on food engineering and on the influence of processing on vitamin content. The third day will be devoted to visits to food manufacturing plants in Chicago. The institute was organized in Cambridge, Mass., in July 1939 following the second conference on food technology, held under the auspices of the Massachusetts Institute of Technology. Samuel C. Prescott, Sc.D., at the Massachusetts Institute, is president; Roy C. Newton, Ph.D., chief chemist, Swift and Company, Chicago, vice president, and George J. Hucker, Ph.D., New York State Agricultural Experiment Station, Geneva, secretary.

Lowest Infant Mortality Rate.—The Bureau of the Census recently issued statistics on the infant mortality rates for 1938, with comparisons of rates in previous years. The general rate for continental United States in 1938 was 51, the lowest since the birth registration area was established in 1915 and undoubtedly the lowest in the history of the country, the bureau states. In 1916 and 1918 the rate was above 100 deaths per thousand live births. Connecticut had the lowest rate, 36.3, and six other states had rates under 40: Massachusetts, Minnesota, Nebraska, New Jersey, Oregon and Washington. The highest rate in 1938 was 108.7 in New Mexico; (the 1939 rate for New Mexico, however, was 145. Other high rates were reported in the following states: Arizona, 98.8; Georgia, 67.7; Louisiana, 67.1; North Carolina, 68.6; South Carolina, 80.3; Virginia, 66.2. Most of these represent considerable reductions from previous years, however, the report shows.

Reunions.—A dinner of the Federation of Catholic Physicians' Guilds will be held at the Biltmore Hotel, New York, Wednesday, June 12. Mr. Lorenz Brosnan, New York, counsel for the Medical Society of the State of New York, and the Rev. Ignatius Cox, S.J., the national moderator of the guilds, will be among the speakers. At 9 a. m. His Excellency Most Reverend Francis J. Spellman, archbishop of New York, will celebrate a mass in the Lady Chapel of St. Patrick's Cathedral for the members of the guilds; at 11 o'clock there will be a meeting of the executive committee of the federation of Catholic Physicians' Guilds at the Waldorf-Astoria Hotel in the club rooms of the Catholic Club on the seventeenth floor. These club rooms will also be used as general headquarters for all members of guilds of other states who wish to avail themselves of the hospitality of the Catholic Club during the American Medical Association convention.—A reunion of former interns and visiting physicians of the Children's Medical Service of Bellevue Hospital will be held at the hospital, Tuesday, June 11. Inspection of the service in the early afternoon will be followed by a general meeting at 4:30. A supper will be served later in the Students' Lounge of New York University Medical College. All former staff members are invited.

CANADA

Canadian Medical Association Meeting.—The seventy-first annual meeting of the Canadian Medical Association will be held in Toronto, June 17-21, at the Royal York Hotel, under the presidency of Dr. Frank S. Patch, Montreal. Among speakers who will address general sessions will be:

Dr. Edmund P. Fowler, New York, The Course and Prognosis of Otitis Media Under New and Old Methods of Treatment.
Dr. Joseph Gardner Hopkins, New York, Urticaria.
Dr. James H. Means, Boston, The Diagnosis and Treatment of Hyperthyroidism.
Dr. James D. Adamson, Winnipeg, Man., Clinical Significance of Bronchial Obstruction.
Dr. John H. Couch, Toronto, Treatment of Injuries and Infections of the Hand.
Dr. Wilfred Alan Curry, Halifax, N. S., Intestinal Obstruction.
Dr. William Fulton Gillespie, Edmonton, Alta., Acute Abdominal Pain.
Dr. Jonathan C. Meakins, Montreal, Shock: Its Recognition and Treatment.
Dr. George Gavin Miller, Montreal, Subtotal Resection for Pericolic Uleer.
Dr. Ray F. Farquharson, Toronto, Anorexia Nervosa.

At the first general session Dr. Patch will deliver his presidential address and Dr. Alan C. Brown, professor of pediatrics, University of Toronto Faculty of Medicine, will deliver the Blackader Lecture.

Lectures for Canadian Medical Officers

The earl of Athlone, governor-general designate of Canada, visited the Middlesex Hospital, London, to meet a group of Canadian medical officers who are attending a course of lectures there. When the first Canadian troops reached this country a series of day-long postgraduate lectures was arranged for 100 of the medical officers by the Middlesex Hospital, whose action they greatly appreciate. Apart from the practical value of the lectures and demonstrations, the courses have given an opportunity for social intercourse and have brought together doctors who have not met since their student days. Lord Athlone, who is a former chairman of the hospital board, the members of the board and the hospital staff met a group of forty Canadian medical officers who were in charge of Colonels R. M. Luton and J. A. Linton.

Substitute for Cod Liver Oil

British production of cod liver oil is almost stopped because most of the trawlers of the industry are in the service of the navy and imports of Norwegian oil have ceased. Up to the beginning of April imports were on a large scale, so that there is no immediate scarcity; but it is necessary to husband supplies. As a wartime substitute it has been decided to add to the British Pharmacopeia an oil expressed from the seeds of *Arachnis hypogaea*, a native of Brazil, which is now extensively cultivated in India, West Africa, China and America. This oil has properties similar to those of olive oil. It will be vitaminized by addition of vitamins A and D to the standard of a good average specimen of the oil expressed from the fresh liver of the cod, *Gadus morrhua*. The addition to the pharmacopeia will embody a formula which will become a legal standard under the food and drugs act, with which vendors must comply in the sale of "medicinal" cod liver oil for human use as distinct from "veterinary" cod liver oil. For the latter there is already an official substitute sanctioned by the Ministry of Food. It consists of a mixture of cod liver oil of high vitamin potency and marine oil.

Imperial Cancer Research Fund

At the annual general meeting of the Imperial Cancer Research Fund Mr. Hugh Lett, president of the Royal College of Surgeons, said that the work of the fund began in 1902 for the purpose of fundamental research on the nature and causes of cancer. Cancer research had been made a general biologic investigation. This policy had placed the fund in a high position scientifically which was recognized in every civilized country. One great advance was the final determination by Bashford and Murray that cancer was at first purely a local condition originating in a group of cells. Cancer research had expanded beyond all expectation. It had been shown that cancer could be caused by application of certain pure chemical substances or physical agents. Therefore some forms could be prevented by appropriate precautions. A recent development was the evidence that hormones might be a decisive factor in the genesis of cancer of the breast.

In the annual report of the fund W. E. Gye, director of the scientific staff, points out that the study of the induction of new growths by application of chemical substances now forms a large part of cancer research. The demonstration that malignant new growths can be induced in almost any part of the body proves that the occurrence of some cancers, at least, is related to environment, which can be controlled, and is not

entirely dependent on some mysterious uncontrollable inborn peculiarity. This aspect of carcinogenesis has occupied the attention of the fund's scientific staff for several years.

Repeated applications of carcinogenic chemical substances produce epithelial hyperplasia and hypertrophy of skin. These changes are not specific but are common to many chronic and healing lesions due to different causes. Yet it is probable that the substances which induce cancer injure the tissues in a peculiar way. Polycyclic hydrocarbons, which are carcinogenic, evoke a characteristic reaction on the second to fourth day after application. Cells and their nuclei swell and cytoplasm becomes vacuolated. Multiplication of cells follows; the increase of cells and nuclei is progressive. Cytoplasmic degeneration appears in some of the cells, while others show signs of recovery. Chemically related noncarcinogenic hydrocarbons do not evoke the reaction.

TUMORS CAUSED BY FILTRABLE VIRUSES

It is only in filtrable tumors that antigenic agents have been found which are not normal constituents of the animal body. These agents, the viruses, are being investigated with great care. Two spontaneous sarcomas were transmitted by filtrates of the original tumors. Transmission of a spontaneous sarcoma by filtrate has not been previously recorded. One of the sarcomas occurred in a fowl which had never been in contact with experimental tumors. These observations controvert the suggestions which have been made that the filtrability of fowl sarcomas is acquired during transplantation or is a result of contamination by the filtrable agent of Rous sarcoma I. A sarcoma which originated near the site of implantation of a transplantable sarcoma was transplanted and subsequently transmitted by filtrates. This transplantation by filtrates contrasts with consistent failures in the laboratory to transmit, in the same way, sarcomas induced in fowls by carcinogenic agents.

Health of Colonial Recruits

Physician-General Blanchard discussed before the Academy of Colonial Sciences the sanitary measures employed on the occasion of the arrival in France of large numbers of men recruited from the French colonies of Asia, Africa and Oceania as soldiers and workers. Above all, the outbreak of infectious diseases had to be prevented among such diversified and susceptible groups. They had to be protected, he said, against their new pathologic environment as the native French must be against the dangers to health of which the former were the possible carriers. Their physical and moral health had to be maintained in the best condition and their selection carefully supervised. Shifts of men on a large scale with change of climate, environment and food constitute conditions favorable to endemics. Since 1938, in anticipation of the arrival of the colonials, health measures had been prepared. Dispensaries had been founded in the colonies, well equipped with prophylactic remedies and possessing important reserves of medicaments and materials. Djibouti on the Red Sea, for example, as well as Dakar on the Atlantic Ocean had been supplied with the personnel and material necessary for the sanitary control with which these centers might eventually be charged. The outbreak of the war proved the efficacy of the measures taken. The antiplague vaccines of the Pasteur Institute of Tananarive, the anticholera vaccines of the Pasteur Institute of Indo-China and the anti-malaria vaccines (for yellow fever) of the Pasteur Institute of Dakar deprived these diseases of their local menace as well as that due to importation. The pneumococcus, to which the colonial natives were susceptible and which had aroused grave anxieties during the war of

1914-1918, had been completely guarded against by an ensemble of sanitary measures pertaining to clothes, transportation, anti-pneumococcus vaccination and the regular use of sulfapyridine. Though cerebrospinal meningitis had acquired a disquieting spread in the tropical zone and the Far East, nevertheless recruits had to be drawn from these regions. Accordingly, antimeningococcus vaccination and sulfonamide therapies were added to the former methods employed in the search for germ carriers and for buccopharyngeal sterilization. Ten million tablets sent by air enabled the carrying out, on an unprecedented scale, of prophylaxis. Necessary supplies against dysentery were on hand. Trachoma, leprosy, trypanosomiasis and venereal diseases had been provided against. Thymol and oil of chenopodium assured against parasites in the intestine. The danger of tuberculosis was guarded against by the systematic examination of the recruits and by inoculation with BCG vaccine by scarification. This huge program of curative and prophylactic sanitation was conducted in close cooperation with British sanitary staffs.

Hypersensitiveness to Postoperative Infection

Postoperative deaths from infection often occur in spite of the fact that the results of surgical intervention were favorable and the patient was well examined and prepared. The symptoms that precede death are high fever, a positive blood culture and the evidence of the bone marrow at necropsy. The impression created is that of an abnormal reaction of the individual. The edematous condition of the lung suggests an anaphylactic shock, a view supported by hematemesis, hematuria and intestinal infarcts. According to Jean Louis Lortat-Jacob, the hypersensitiveness that seems to be at the bottom of these accidents might be "the form that is intolerant of immunity." Hypersensitiveness not only is determined by albuminoid substances or serums but is observed likewise in the presence of infectious germs. Lortat-Jacob recently submitted multiple proof in a significant experimental study.

Immunity and hypersensitiveness are opposed to each other but yet capable of succeeding each other in the same person. Every individual that is a carrier of germs or is hypersensitive may, under certain conditions, become the seat of grave manifestations of hypersensitiveness to infection, specific or non-specific. As Reilly has demonstrated, the vegetative nervous system plays a preponderant part. Clearcut vagotonia ought to be considered as favorable to reactions of hypersensitiveness. This vagotonia should be determined by the investigation of the oculocardiac reflexes, by atropine or by intradermal reactions with polyvalent vaccines. Preventive and curative therapy consists in stimulating the sympathetic nerve and avoiding acidosis rather than in insisting on vaccinations, which should be reserved for subjects presenting a positive intradermal reaction. Surgical intervention is performed only when intradermal reactions have become negative.

Erythroblastosis

Besides erythroblastic syndromes such as those of cancer and tuberculosis of the spleen, one observes more and more pathologic conditions characterized by a "dysgenic hyperplasia of the bone marrow" that involve cryptogenic processes. The latter are not always accompanied by lesions or hepatosplenic symptoms but are often limited to foci of erythroblastic myeloid metaplasia. Professor Pittaluga of Madrid reported to the French society of hematology a case of grave anemia with fever and subicterus, enormous increase in the size of the spleen and liver, profound disturbances of water and fat metabolism and progressive decrease of erythrocytes of hyperchromatic tendency but without megalocytosis, with leukopenia and an increasingly pronounced erythroblastosis that dominated the pathologic picture until death set in. This case, minutely studied with the aid of laboratory technics, gave Pittaluga an

opportunity to elaborate his views on erythroblastosis and its diagnosis. There is a difference, he said, between erythroblastic and reticulocytic reactions. Reticulocytes do not obey the same factors as erythroblasts. Cryptogenic erythroblastosis in adults presents a pathologic background, with simultaneous lesions of the myeloid blood system, spleen and liver and metabolic alterations. These changes are polymorphic and regularly associated with massive and persistent erythroblastosis. The etiology of this disease may be infectious, since a number of symptoms point in that direction. However, the blood culture is negative. The causative agent may also be sought in deficiency of nutrition, of vitamin assimilation and of the assimilation of certain primary groups of food substances, to which constitutional factors point. Intoxication may also be responsible. Dysfunction in the assimilation of the vitamins, notably of B₂, of A and of D, is probable. Among intoxications tar derivatives have been suspected. Constitutional factors, however, cannot be excluded; etiologically blood diseases must be referred to these factors. Several blood diseases, the speaker said, were due to constitutional disorders and had their root in a morbid heredity. Accordingly, essential erythroblastosis must be considered a hereditary disease that is belatedly activated perhaps by an accidental infection. It involves a profound and complex biochemical and physicochemical change of remote origin and has a fatal prognosis.

Midwives, Nurses and Nurse Maids

A sharper distinction is to be drawn hereafter between midwives, nurses and nurse maids. Nurses as well as nurse maids may not be officially certified as midwives, and vice versa. Certification as a midwife automatically cancels certification as regular nurse or child nurse. There is, however, nothing to prevent change from one of these occupations to the other. Nurses may not take over a maternity case or the care of a healthy newborn infant if they have handled a regular case three days previously. Neither may a nurse take over the case of a healthy lying-in woman until ten days have elapsed after delivery. The training of nurse maids (Säuglings- und Kinder-schwester) has likewise been reorganized. In addition to a satisfactory examination, evidence must be presented of Aryan descent and political reliability. After the examinations, the nurse must serve six months in public welfare work and in a children's clinic. To be eligible for training the applicant must be 18 years old and have spent one year in domestic service in a family, an institution or a school. The training lasts one and one-half years and requires a state examination. The title of child nurse is legally protected against fraudulent use. Midwives may hereafter exercise their occupation until they reach the seventieth year. Prolongation of service may be officially granted in exceptional cases, conditioned on physical and mental vigor.

Rabies

According to a report of the department of the interior, rabies is prevalent in the eastern sections of present Germany. Regulations have been adopted for its control and the education of the population. For this an educational film is used. Dogs appearing in public must be kept on the leash.

Malformations

A new order of the department of the interior requires that malformed infants be reported to the respective board of health. These deformities include idiocy and mongolism, especially in combination with blindness and deafness, microcephalus, grave or progressive hydrocephalus, and malformations of all kinds.

BUENOS AIRES

(From Our Regular Correspondent)

April 26, 1940.

Tuberculosis Control

Recently in these columns information was given pertaining to the control of tuberculosis (*THE JOURNAL* May 4, p. 1822). According to a report for the city of Buenos Aires covering the year 1939, by Dr. A. A. Raimondi, the number of beds in the municipal tuberculosis hospitals has not been increased in accordance with existing needs. In 1939, 2,794 persons died of tuberculosis, 1,664 men and 1,130 women. However, the mortality rate for tuberculosis has greatly decreased during the last decade. Visits were made in 2,463 homes in which death from the disease had occurred. Of 609 children exposed to the infection 263 were found diseased. Numerous organizations in Buenos Aires are engaged in promoting and extending the control of tuberculosis.

Hookworm Disease

In 1924 a service bureau of the national department of public health was organized in Corrientes, the province most affected with hookworm disease. In 1934 a law was passed making treatment and prophylaxis compulsory in Argentina. Those suffering from the disease and unable to prove that they are under private treatment are treated without charge at the government stations. Under certain conditions patients may be isolated in their homes. Hygienic regulations have also been prepared for homes and factories.

Two Argentine gunboats have been fitted out with laboratories for scientific tests to be made by a commission headed by Dr. Carlos Fonso Gandolfo, professor of infectious diseases in Buenos Aires, and consisting of a staff of more than twenty physicians and eighty student helpers to undertake an investigation of the infection. This investigation is to last two weeks. For the duration of this investigation, twenty additional laboratories will be set up. In addition, lectures, films and illustrated printed material will be used to educate the population. This investigation has the support of the responsible health boards and of the army and navy, and much is expected from it. The national health board treated 36,700 persons in these regions during the last year. Lack of cooperation on the part of the population and laxness in enforcing existing penalties have interfered with the degree of disease control desired.

Congress of Otorhinolaryngologists

The Congress of Otorhinolaryngologists, the first of its kind, took place in Buenos Aires, April 21-25. Its origin goes back to a suggestion advanced in 1938 by Brazilian specialists meeting in Rio de Janeiro. Dr. Eliseo V. Segura, professor of otorhinolaryngology in Buenos Aires, presided. Official delegations of Brazil, Chile, Peru, Uruguay and Venezuela participated. The papers discussed infections of the accessory nasal cavities and their treatment, conservative surgery of the middle ear, otorhinolaryngologic localization of blastomycosis, and the physiopathology of the inferior portion of the labyrinth. Two surgical sessions were also conducted with practical demonstrations by visiting surgeons. Professor Segura pointed out that South American medical science had come into its own and could give an account of itself in contributing independently to the progress of medicine, free from the tutelage of Europe. The congress was well attended. The next congress will meet three years hence in São Paulo, Brazil, with Prof. de Paula Santos as its presiding officer.

Nutrition in Chile

An investigation on nutrition was conducted in Chile by Carlo Dragoni and Etienne Burnet, an expert on hygiene from the League of Nations, among 593 families involving 3,383 persons (*Revista chilena de higiene* 1:409 [Oct.-Dec.] 1938).

Forty-one per cent of these families lived in Santiago de Chile. Expenditures for food represented 78.3 per cent of the total expenditures. In general, wages paid in many of the large mining, textile and construction industries, the report indicates, permit a standard of living on a modest and sufficient scale. In the small industries, trades and small business, however, living conditions are largely unsatisfactory. Four meals a day are customary. For breakfast a warm beverage is always served, such as coffee, tea and mate together with bread. Butter is rarely used. The afternoon repast has not the same significance as breakfast and consists likewise of a warm beverage and bread. The same types of food are represented in the two principal meals. In 43 per cent of the meals the cazuela, the national dish consisting basically of meat and fish, is found. A comparative analysis showed that more meals had a meat basis than a vegetable basis, such as beans and potatoes (7,454 vs. 4,971). Beverages mostly in use are tea and sugared coffee. The use of wine is rare. An adequate or plentiful nutritional status was found in 180 of the 593 families, comprising 924 persons. In 131 (764 persons) it was just sufficient; 280 families (1,689 persons) were more or less underfed. Hence, according to this investigation, half of the average population suffer from malnutrition. According to the principles set up in London by the conference on nutrition of the League of Nations, the so-called protective foods should constitute the basis, and cereals and sugar should be regarded as supplementary energy foods. In Chile the old nutritional conceptions still prevail.

Personals

Prof. Bariano R. Castex, professor of internal medicine, succeeded Dr. Alberto Peralta Ramos, professor of gynecology, as president of the Academy of Medicine in Buenos Aires.

Dr. Nicanor Palacios Costa, professor of gynecology, succeeded Prof. José Arce, retiring professor of surgery, as dean of the medical faculty in Buenos Aires.

Dr. Enrique Castano was appointed professor of clinical urology in Buenos Aires in place of Professor Maraini, who recently died. Dr. Atilio J. Costa was named professor of surgical technics in place of Prof. Bosch Arana, deceased.

Dr. José A. Saralegui, associate professor of the faculty of medicine, was appointed director of the municipal institute of radiology and physical therapy in Buenos Aires. He has studied in the United States.

Prof. Ramón Doria was appointed dean of the medical faculty in Asunción, Paraguay.

Marriages

EDWARD MARSHALL SANDIDGE, Pleasant View, Va., to Miss Nellie Penn McDaniel of Sandidges, April 3.

ERNEST LYNWOOD BAGBY to Miss Barbara Lucille Riddell, both of Richmond, Va., April 27.

LOUIS BENJAMIN SHEPPARD to Miss Callie Helen Nolde, both of Richmond, Va., April 25.

KENNETH B. WALBORN to Miss Annie Evangeline Pool, both of Dallas, Texas, March 24.

LEOPOLDO E. LOPEZ to Miss Edith Gil Santana, both of Caracas, Venezuela, May 11.

FRANK SAMUEL GRIFFIN JR., Liberty, Texas, to Miss Helen Shattuck of Alto, March 10.

DONALD HARPER LEEPER JR. to Miss Fofa Mezitis, both of Washington, D. C., in April.

LEWIS ALEXANDER VANCE, Boston, to Miss Jane Kelley of Brookline, Mass., April 20.

HUGH H. TROUT JR. to Miss Elizabeth Page Brown, both of Roanoke, Va., April 6.

E. J. TUCKER JR., Liberty, Texas, to Miss Lola Dickson, March 10.

Deaths

Charles Benjamin Wright * member of the Board of Trustees of the American Medical Association, died at his home in Minneapolis, May 31, of myocarditis and emphysema, aged 63.

Dr. Wright was born Nov. 3, 1876, in Kemptville, Ontario. With his parents he moved to Grand Forks, N. D., and was graduated from the University of North Dakota in 1898, at which time he was a star on the University of North Dakota football team. He then entered the medical department of Johns Hopkins University, receiving his degree in medicine in 1902 and becoming house officer at the Johns Hopkins Hospital. After graduate study abroad in Vienna, Berlin and Rome in 1913 and 1914 he became associate professor of medicine at the University of Minnesota Medical School from 1920 to 1935 and had been professor of clinical medicine since 1935.

He was a fellow of the American College of Physicians and member of the Central Society for Clinical Research and also a member of the Societies of Internal Medicine and of Pathology in Minnesota. He had from time to time published scientific contributions on rectal bleeding, histamine, undulant fever and microcytic anemia.

Early in his career Dr. Wright became interested in the work of organized medicine, serving as a member of the House of Delegates of the American Medical Association as a representative from Minnesota, from 1930 through 1933. In that year he was elected a member of the Board of Trustees for a term of five years and was reelected for another five year term in 1938. At the time of his death he was chairman of the Executive Committee of the Board.

Dr. Wright was devoted to the work of the American Medical Association, giving unstintingly of his time and his thought to the numerous problems which have concerned the profession in recent years. His loyalty, his impatience with deceit and his aggressiveness on behalf of a free medical profession made him distinguished as a leader.

Joseph Elzear Lamoureux, Lowell, Mass.; Laval University Faculty of Medicine, Quebec, 1893; School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, 1893; member of the Massachusetts Medical Society; formerly chairman of the school committee; on the staff of St. Joseph's Hospital; aged 70; died, March 16, of carcinoma of the throat.

Frederic Bertrand, Sherbrooke, Que., Canada; School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, 1905; Laval University Faculty of Medicine, Quebec, 1906; fellow of the American College of Surgeons; on the staff of Hôpital General St. Vincent de Paul; aged 58; died, February 9, of myocardial infarction.

Harold Philipp Kuhn * Kansas City, Mo.; University of Kansas School of Medicine, Kansas City, 1906; fellow of the American College of Surgeons; professor of oral surgery, Kansas City-Western Dental College; attending surgeon to St. Luke's and Kansas City General hospitals; aged 59; died, April 15, of malignant hypertension and chronic nephritis.

James Thomas Jeter, Santuck, S. C.; Medical College of the State of South Carolina, Charleston, 1890; member of the South Carolina Medical Association; formerly member of the state senate; served during the World War; aged 72; died, April 12, in the Veterans Administration Facility, Columbia, of prostatic hypertrophy, uremia and chronic cystitis.

Guy Logan Qualls * Colonel, M. C., U. S. Army, Fort Benning, Ga.; St. Louis University School of Medicine, 1909; entered the medical corps of the United States Army in 1912; served during the World War; after passing through the various grades became a colonel in 1939; fellow of the American College of Surgeons; aged 57; died recently.

CHARLES B. WRIGHT, M.D.,
1876-1940

Paul Stearns Mertins * Montgomery, Ala.; Harvard Medical School, Boston, 1900; member of the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; on the staff of St. Margaret's Hospital; aged 63; died, April 10, of cerebral hemorrhage, uremia and hypertension.

L. Leo Doane, Highland Park, Ill.; College of Physicians and Surgeons, Baltimore, 1886; member of the Medical Society of the State of Pennsylvania and the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; aged 83; died, April 11, of acute dilatation of the heart.

Benjamin Rammel Veasey * Wilmington, Del.; Jefferson Medical College of Philadelphia, 1894; fellow of the American College of Surgeons; formerly state senator; at one time member of the board of education; on the staff of the Wilmington General Hospital; aged 80; died, April 6, of gastric carcinoma.

Arthur William Karch, Monroe, Mich.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1912; member of the Michigan State Medical Society; mayor; on the staff of the Monroe Hospital; aged 52; died, April 29, of gangrenous diverticulitis and myocarditis.

James Blackman Woodruff * New Orleans; University of Tennessee Medical Department, Nashville, 1900; member of the Tennessee State Medical Association; acting assistant surgeon, U. S. Public Health Service; aged 63; on the staff of the U. S. Marine Hospital, where he died, April 22.

Leonard Herbert Stewart * Kalamazoo, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1897; past president of the Kalamazoo Academy of Medicine; trustee of the Kalamazoo College; aged 82; died, April 21, in the Borgess Hospital of pyelitis and septicemia.

Arthur L. Oilar, Russiaville, Ind.; Indiana University School of Medicine, Indianapolis, 1913; served during the World War; formerly epidemiologist for the state board of health, and health officer of Talbot County, Md.; aged 48; died, April 25, of coronary occlusion.

Robert John Jones * Greenfield, Ohio; Medical College of Ohio, Cincinnati, 1895; past president of the Highland County Medical Society; fellow of the American College of Surgeons; one of the founders and on the staff of the Greenfield Hospital; aged 68; died, March 11.

James Alexander Graham, Tagbilaran, Philippine Islands; Baltimore Medical College, 1897; member of the Philippine Islands Medical Association; a medical missionary; also a minister; superintendent of the Presbyterian Mission Hospital; aged 65; died, March 25.

Asa Wesley Graves, Lacey Spring, Va.; Medical College of Virginia, Richmond, 1910; member of the Medical Society of Virginia; served during the World War; aged 61; died, April 12, in the Rockingham Memorial Hospital, Harrisonburg, of diabetes mellitus.

Theodore Gervais, Berthierville, Que., Canada; School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, 1893; Laval University Faculty of Medicine, Quebec, 1893; aged 71; died, February 18, of pneumonia.

James R. Roberts, Hamilton, Ont., Canada; McGill University Faculty of Medicine, Montreal, Que., 1901; vice president of the International Society of Medical Health Officers; medical health officer; served during the World War; aged 61; died, March 15.

Frederick Newton Whitehorse, New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1895; New York Homeopathic Medical College and Hospital, 1898; aged 67; died, April 6, of coronary thrombosis.

Guy Arnold McCormack, Little Rock, Ark.; University of Arkansas School of Medicine, Little Rock, 1914; member of the Arkansas Medical Society; veteran of the Spanish-American and World wars; aged 66; died, April 6, of chronic myocarditis.

George De Loach Waller Sr., Bessemer, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1899; member of the Medical Association of the State of Alabama; aged 69; died, April 12, of hypertensive heart disease.

Emmett Earle Linville, Mount Olivet, Ky.; Hospital College of Medicine, Louisville, 1907; member of the Kentucky State Medical Association; served during the World War; aged 57; died, April 28, of coronary occlusion.

Thomas Youngman, Coral Gables, Fla.; Hahnemann Medical College and Hospital of Philadelphia, 1904; at one time bank president; formerly president of the board of health of Ventnor, N. J.; aged 59; died, March 11.

James B. Vaughan ☉ Monroe, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1901; medical director of the Vaughan-Wright-Bendel Clinic; aged 62; died, April 14, of acute dilatation of the heart.

John A. Mann, Wellington, Mo.; St. Louis Medical College, 1876; member of the Missouri State Medical Association; at one time bank president; formerly mayor; aged 88; died, April 20, of hemorrhage of the bladder.

Edward N. Gerard, Leonard, Mo.; University Medical College of Kansas City, 1895; member of the Missouri State Medical Association; aged 70; died recently in the Grim-Smith Hospital, Kirksville, of uremia.

Peter Winston Prather, Woodland Mills, Tenn.; University of Louisville (Ky.) Medical Department, 1906; member of the Tennessee State Medical Association; aged 61; died, April 14, of coronary thrombosis.

Edward S. Dwight, Smyrna, Del.; Yale University School of Medicine, New Haven, 1876; member of the Medical Society of Delaware; past president of the Kent County Medical Society; aged 86; died, March 17.

Ella Virginia Cameron, Philadelphia; Eclectic Medical College of the City of New York, 1895; aged 75; died, March 17, in a hospital at Greystone Park, N. J., of chronic myocarditis and mitral stenosis.

David Bernhard Hirschfeld ☉ New York; Cornell University Medical College, New York, 1910; aged 60; died, April 8, in the Mount Sinai Hospital of infection of the hand and suppurative phlebitis.

William E. Braun, Eldorado, Ill.; College of Physicians and Surgeons, Keokuk, Iowa, 1878; aged 88; died, April 29, in the Ferrell Hospital as the result of injuries received when struck by an automobile.

William Kenney, San Francisco; University of California Medical Department, 1905; assistant clinical professor of medicine at the Stanford University School of Medicine; aged 61; died, March 3.

Elliott Irving Osgood, Hiram, Ohio; Cleveland University of Medicine and Surgery, 1897; for many years a medical missionary in central China; aged 69; died, April 13, of cerebral hemorrhage.

Edward Routh Hines, Rocky Mount, N. C.; Medical College of the State of South Carolina, Charleston, 1916; aged 59; died, April 3, of ruptured esophageal varix with cirrhosis of the liver.

George Thomas Tubb, Aberdeen, Miss.; Memphis (Tenn.) Hospital Medical College, 1899; member of the Mississippi State Medical Association; aged 71; died in April of carcinoma of the liver.

George Guy Bailey ☉ Ipswich, Mass.; Harvard Medical School, Boston, 1892; on the staff of the Benjamin Stickney Cable Memorial Hospital; aged 75; died, March 30, of coronary thrombosis.

Parrott Rastus Hardee, Durham, N. C.; College of Physicians and Surgeons, Baltimore, 1885; aged 78; died, April 14, of bronchopneumonia and carcinoma of the stomach with metastasis.

Don Duff Campbell, Miami Beach, Fla.; University of Toronto Faculty of Medicine, Toronto, Canada, 1904; aged 65; died, March 27, in St. Francis Hospital of cirrhosis of the liver.

Randolph D. Jones, Elza, Ga.; University of Georgia Medical Department, Augusta, 1899; member of the Medical Association of Georgia; aged 63; died in March of heart disease.

Robert Lee Page, Batesville, Va.; Bellevue Hospital Medical College, New York, 1884; member of the Medical Society of Virginia; aged 76; died, April 29, of cerebral hemorrhage.

Lyman Jairus Clements ☉ Washington, D. C.; George Washington University School of Medicine, 1906; aged 74; died, April 12, of carcinoma of the parotid gland.

Edwin Rhinehart Yancey, Monroe, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1910; served during the World War; aged 53; died, March 16.

Ernest Ray Reynolds ☉ Chicago; Northwestern University Medical School, Chicago, 1900; on the staff of the Englewood Hospital; aged 65; died, April 24, of coronary occlusion.

Haydn Mozart Simmons, San Francisco; University of California Medical Department, San Francisco, 1901; aged 65; died recently in St. Francis Hospital of lobar pneumonia.

Mitchell C. Shelton, Joplin, Mo.; Barnes Medical College, St. Louis, 1894; member of the Missouri State Medical Association; aged 72; died, April 24, of coronary occlusion.

Josephine Ida Burbeau, Newark, N. J.; New York Medical College and Hospital for Women, New York, 1885; aged 82; died, March 25, in East Orange of cerebral hemorrhage.

Garrett Bancroft Breckinridge Larkeque, Pownal, Vt.; Homeopathic Hospital College, Cleveland, 1893; aged 68; died recently of chronic myocarditis and chronic arteritis.

Samuel Guy McCune, McKeesport, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1899; aged 65; died recently of cerebral hemorrhage and influenza.

Hugh Wilmer Duke, Amarillo, Texas; Baylor University College of Medicine, Dallas, 1901; justice of the peace; aged 66; died, March 23, of chronic myocarditis.

John Harvey ☉ Bryn Mawr, Pa.; Jefferson Medical College of Philadelphia, 1910; for many years on the staff of the Bryn Mawr Hospital; aged 57; died, March 18.

William Edward Segrest, Sardis, Miss.; Memphis (Tenn.) Hospital Medical College, 1900; aged 64; died, April 10, of cerebral hemorrhage and arteriosclerosis.

James Malcolm Miller, Villa Grove, Ill.; St. Louis University School of Medicine, 1905; aged 78; died, April 4, of chronic myocarditis and arteriosclerosis.

Albert Charles Geyser, Huntington, N. Y.; Bellevue Hospital Medical College, New York, 1896; aged 75; died, March 5, of pneumonia and arteriosclerosis.

Frederick E. Hammond, French Lick, Ind.; Hospital College of Medicine, Louisville, Ky., 1898; aged 68; was found dead in April of heart disease.

Tell John Berggren, San Diego, Calif.; American Medical Missionary College, Chicago, 1906; aged 63; died, March 10, of cardiac decompensation.

Daniel B. Rigdon, Cheyenne, Wyo.; College of Physicians and Surgeons, Keokuk, Iowa, 1882; aged 92; died, April 18, of gastric hemorrhage.

James A. Gold, Frankstown, Pa.; Homeopathic Hospital College, Cleveland, 1887; aged 79; died recently in Hollidaysburg of arteriosclerosis.

William Hermann Schultz, Cleveland, Tenn.; Chattanooga (Tenn.) Medical College, 1898; aged 66; died, April 28, of coronary occlusion.

George C. Wegefarth, Baltimore; Baltimore Medical College, 1897; aged 64; died, March 22, in the Johns Hopkins Hospital of peritonitis.

Claude Frank Hayes, Los Angeles; Hahnemann Medical College and Hospital, Chicago, 1897; aged 66; died recently of coronary thrombosis.

Ernest Bruce Hatch ☉ Miami, Fla.; Atlanta College of Physicians and Surgeons, 1910; aged 54; died, April 2, of coronary thrombosis.

Zeleanor E. Crawley, Columbia, Miss.; University of Nashville (Tenn.) Medical Department, 1900; aged 65; died, April 10, of uremia.

Roland Rufus Johnson, Brooklyn; Long Island College Hospital, Brooklyn, 1907; aged 58; died, April 29, of acute coronary occlusion.

Maurice G. Slocum, Kansas City, Mo.; Keokuk (Iowa) Medical College, 1897; aged 65; died, April 12, of cardiac decompensation.

William F. Perry, Los Angeles; Kentucky School of Medicine, Louisville, 1885; aged 87; died recently of hypostatic pneumonia.

Louis John Feid, Cincinnati; Cincinnati College of Medicine and Surgery, 1893; aged 73; died, April 22, of coronary occlusion.

Sylvina Apphia Abbott, Cranston, R. I. (licensed in Massachusetts in 1894); aged 76; died, April 12, of angina pectoris.

William Dyer Gardner, Plain City, Ohio; Starling Medical College, Columbus, 1900; aged 64; died, April 30, of heart disease.

Alphonso L. Ruffe, Grand Rapids, Mich.; Chicago Homeopathic Medical College, 1887; aged 86; died, April 13, of uremia.

of a patient with Banti's disease and hematemesis, with apparent relief. Rhoads and Stein (*Am. J. Dis. Child.* 56:119 [July] 1938) ligated the coronary vessels and removed the spleen from a boy with Banti's disease who had bled seriously from esophageal varices demonstrated by roentgenograms. Bleeding stopped and subsequent examination revealed reduction in the size of the varicosities. L. R. Dragstedt has removed the spleen, ligated the veins at the cardia and injected 5 cc. of sodium morrhuate into the veins above the ligatures in three cases of portal hypertension, splenomegaly, esophageal varicosities and repeated severe hemorrhages. Two of the patients remained well for periods of two and four years, and roentgenograms revealed the absence of varicosities which were demonstrated before operation. In the third case the varicosities remained just as large after the operation and injection, and death occurred later of hemorrhage.

"BILIOUS FEVER"

To the Editor:—In the early history of Davenport, according to the records, a prominent citizen died of "bilious fever." Within two weeks, two other members of the same family died of the same thing. I should like to know if at that time (about 1835) "bilious fever" was a common diagnosis. Was it considered a clinical entity? From our present knowledge what would be the probable diagnosis? It may have been malaria, which was prevalent here in those days, except that three deaths so close together would indicate some contagious disease. Typhoid was common, but the doctors at that time were not often fooled with this diagnosis.

W. H. Rendleman, M.D., Davenport, Iowa.

ANSWER.—The diagnosis "bilious fever" was popularized by Maximilian Stoll (1742-1787), who regarded all fevers as due to "gastrobilious" impurities. William Buchan, of Edinburgh, whose Treatise on the Prevention and Cure of Diseases was published in Philadelphia in 1784, states that "when a continual, remitting or intermittent fever is accompanied with a frequent or copious evacuation of bile, either by vomit or stool, the fever is denominated bilious." His description of "bilious fever" suggests most strongly typhoid fever. Dr. John Sappington in his Theory and Treatment of Fever, published in 1844, devotes a chapter to the "common bilious or bilious remittent fever." Sappington's description also suggests typhoid. He described a long continued fever with delirium, diarrhea, brown coated tongue, full soft pulse and great thirst. Charles Murchison, in his treatise on the Continued Fevers of Great Britain (London, 1873), lists "bilious fever" as a synonym for typhoid.

PROBABLE MILIUM OF EAR

To the Editor:—A young man under treatment for a duodenal ulcer called my attention to a group of white indurated papules on the back of each ear. At present there are about thirty on each ear but he states that there have been many more than that at times. They vary in size from about 0.1 to 0.5 cm. His wife noticed them about three months ago and he states that she expressed some drops of clear secretion from them which she noticed had an offensive odor. He says that at weekly intervals she has so expressed them, the last time four days previous to his present visit. I could express no visible drops of secretion but on rubbing my finger firmly over them enough was expressed to corroborate her statement as to the odor. It was offensive and required brisk rubbing with soap and water to remove. A small incision in one of the larger papules did not produce any appreciable amount of secretion at this time. There is present a mild oily seborrhea and a mild acne vulgaris. The young man is of dark complexion. He has been using acetylsalicylic acid and acetylsalicylic acid compound frequently, from 10 to 30 grains daily (0.65 to 2 Gm.), for several months for a unilateral (right side) headache of as yet undetermined origin. A general examination following a gastric hemorrhage in November 1938 revealed an epigastric hernia and a duodenal ulcer. Previous to the hemorrhage he had had the same type of headache as now and a mild constipation but none of the usual symptoms of ulcer. Placed on strict medical management he felt better generally, the headaches were relieved and an x-ray examination in January 1939 was negative. There was no evidence of the previous ulcer. He was allowed a more liberal diet until the return of the headaches but has obtained practically no relief from a strict medical management since. In the general examination, blood studies including a Wassermann test were normal. His eyes and sinuses showed no abnormalities. I have not seen a similar eruption with acne or seborrheic dermatitis previously. Is it probably a part of the picture of one of these entities or a separate condition of the sebaceous or oil glands? I mention his general condition at some length as I found nothing in several textbooks on dermatology by which I could make a definite diagnosis.

M.D., Minnesota.

ANSWER.—White hard papules from 0.1 to 0.5 cm. in diameter suggests milium, which means millet seed. It is true that these papules seldom exceed 0.2 cm. in diameter, but they sometimes grow larger than this. It is these large ones whose content of subcutaneous matter is most apt to degenerate, soften and smell bad. If this is the correct diagnosis, the odor resembled that of butyric acid, which is offensive and persistent enough. The small incision mentioned should have freed the contents of the papule; but it is likely that pressure was needed to bring out the hardened sebum. After cleansing the skin with alcohol,

one can incise the skin covering the papule and press out the pearl-like contents. The lesions seldom recur. The daily application of lotio alba (sulfurated potassa 1 Gm., zinc sulfate 1.5 Gm. and rose water to make 30 cc.) will aid in preventing their formation, which results from the overgrowth of the horny layer, a factor in the causation of acne.

TREATMENT OF PINWORM INFESTATIONS

To the Editor:—Do threadworms ever get into the urinary bladder? A 7 months old baby has them in the bowels, nose and mouth. The parents also have them. I am using chenopodium oil on the baby internally and 1 per cent chenopodium oil in olive oil in the nose. I am not sure that the worms are in the bladder but the mother states that they are found under the foreskin. Please send information.

W. A. Brand, M.D., Redwood Falls, Minn.

To the Editor:—Can you inform me what the new and improved methods of therapy are for pinworm infestation referred to by Willard H. Wright in the March 1939 issue of *Hygeia*?

G. O. Gronhoyd, M.D., Santa Paula, Calif.

ANSWER.—A search of the literature has failed to reveal an authenticated case of threadworms (*Enterobius vermicularis*) in the bladder. However, the gravid female worms after their emergence from the anal canal frequently migrate extensively. In women they may enter the vagina and have been found in the uterus, fallopian tubes and the peritoneal cavity. It is suggested that the present treatment of the infant be supplemented with enemas every other night for a period of from three to four weeks. For this purpose saline enemas may be used, although the use of enemas consisting of a 1:2,000 solution of hexylresorcinol in water will give better results. Some children are particularly susceptible to the local irritating properties of hexylresorcinol. In such event the drug should be further diluted. It would be advisable to treat both parents and all other infected members of the family at the same time in order to reduce opportunities for reinfection. For this purpose the use of gentian violet medicinal N. N. R. is indicated.

At the present time the most effective treatment for the removal of pinworms (*Enterobius vermicularis*) consists in the administration of gentian violet medicinal N. N. R. Either enteric coated or water soluble coated tablets may be used. The dose of gentian violet for adults is 1 grain (64 mg.) three times a day before meals for eight days; the treatment is discontinued for a week and then repeated for an additional period of eight days. The dosage for children over 3 years of age is based on 0.01 Gm. a day for each year of apparent (not chronological) age. This daily dosage should be divided into three parts. The treatment is carried out in the same manner as for adults. About one third of cases treated with gentian violet show some reaction, consisting usually of nausea, vomiting, diarrhea, constipation and slight abdominal pain. If reactions ensue, it is advisable to reduce the dosage or withhold treatment for a day or two until the patient returns to normal. Gentian violet is contraindicated in moderate to severe heart, hepatic and renal disease, in gastro-enteritis, in pregnancy and in the presence of febrile or debilitating diseases. The patient should abstain from alcohol during the period of treatment. Persons suffering from ascariasis should be treated for the removal of ascarids before the administration of gentian violet.

In controlling pinworm infestation within the household, it is necessary to treat all infested members simultaneously in order to reduce opportunities for reinfestation through eggs scattered around the house by nontreated individuals.

COLORED PAPER AND VISUAL DISABILITY

To the Editor:—I have been asked to make a report on the effect of various colored paper used in clerical work on the eyes of the workers. The state social welfare department uses papers of a distinct color for each department under its supervision. These include pink, green and yellow as well as white. The departments using the pink seem to have a greater incidence of visual disabilities than the others. Can you refer me to any recent literature on this problem?

William A. Pettit, M.D., Los Angeles.

ANSWER.—In all probability, the greater visual disabilities in the department using pink paper are coincidental rather than the result of the color of the papers employed. There has been considerable discussion on this topic off and on for the past twenty-five years and the majority view is epitomized in the various books by Matthew Luckiesh, of Nela Park. The first of these was published in 1915 and since then some seven of his publications have touched more or less on this topic. All of the volumes have been published by the Williams and Wilkins Company, of Baltimore.

PROBABLE ERYTHROCYANOSIS FRIGIDA

To the Editor:—A stenographer aged 22 has suffered for ten years with severe pain and occasional slight redness of the extensor side of the lower third of the lower part of the left leg. This severe pain appears every year as soon as cold weather sets in. It disappears with the beginning of warm weather. The pain is so severe at times that the girl is unable to work and loses considerable weight during the winter months. There is no itching. Cold in summer, such as cold water in bathing, does not produce the pain. Heat never relieves it. The right leg was never painful, even in the coldest weather. The girl has no other symptoms. Menstruation is regular. Results of physical examination were always negative. In the region of the pain at times a bluish red discoloration without induration could be seen; but these changes were practically the same in the right leg. The pulses of the popliteal, posterior tibial and dorsalis pedis arteries are of good quality in both legs. There are no changes of sensory functions, including the vibratory sense. The blood pressure in the two legs is equal and normal. Results of urine examination number 3,900,000 and white blood cells 10,000 with the following differential count: band forms 2, segmented cells 52, lymphocytes 35, monocytes 4, eosinophils 4; the bleeding time is two and one-half minutes, the coagulation time six and one-half minutes and the Wassermann reaction negative. The condition has been treated as frost bite for years without any success. The question arises Do we have to deal in this case with changes in the vascular system? The lack of objective signs and the fact that cold speak against this diagnosis. Please advise me as to diagnosis and treatment.

M.D., Connecticut.

ANSWER.—The condition described fits into the clinical picture of a malady less frequently seen here than on the European continent, namely erythrocyanosis frigida. In this lesion the skin looks much like that observed in the same etiologic factors, poliomyelitis, and it is probable that the amount of fat an insufficient venous return, an increase in the amount of fat in proportion to muscle and exposure to cold, are in operation in both diseases. As in poliomyelitis, the most severe cases show indurations and ulcerations and there gradually develops a great thickening of the subcutaneous tissues above the ankles. Abortive poliomyelitis and the presence of spina bifida occulta often associated with erythrocyanosis and pes cavus should be ruled out. This condition is most frequent in girls at about the time of puberty, and the milder forms become less troublesome with advancing years. Those with the painful and especially with the indurated or ulcerated type should be subjected to a lumbar sympathectomy. Late results of this operation are satisfactory.

MILD DIABETES

To the Editor:—A rather obese man about 45 years of age has had glycosuria for six years. Until about a year ago his fasting blood sugar was around 120 or less but now is 140. He has never taken any insulin but was and is able to remain sugar free (urine) by rather strict limitation of "starchy" foods with no sweets. Within the past year he has begun eating starchy foods occasionally and when he does so his urine shows 2 per cent sugar on the following forenoon. He was in apparently perfect health, felt good, lost some weight (but not too much) and had plenty of energy on his low carbohydrate diet. Of course he occasionally complained of some hunger. Now one of his nephews has finished medical school and advises him by all means to take insulin and increase the carbohydrate intake, while I have been advising him to stick to the low carbohydrate diet with no insulin unless diabetes becomes more severe. He is a druggist, is 5½ feet (168 cm.) tall and weighs from 190 to 195 pounds (about 87 Kg.). Which advice is right?

M.D., Louisiana.

ANSWER.—With such mild involvement the patient has a good prospect to live out the normal life expectancy, which at 45 years is twenty-five years for men. To do this and to avoid complications, he should take advantage of protamine zinc insulin once a day, which surely would allow him daily between 150 and 200 Gm. of carbohydrate, perhaps more, with sufficient protein, from 80 to 100 Gm., and fat sufficient for caloric needs. Gradual, slow reduction of weight on the diabetic condition but for its probably beneficial influence on the body in general, also to prevent harmful effects of obesity on the immediate welfare of the man, but one should plan also for the twenty-five years more to come.

PROSTIGMINE AND PITRESSIN WITH MORPHINE

To the Editor:—Are prostigmine methylsulfate and pitressin compatible with morphine and are they used simultaneously with morphine in postoperative cases such as cholecystectomies?

ANSWER.—Pitressin and prostigmine are used to relieve the bowel and bladder atony following abdominal section. The increase in tone of the muscular coat of the intestine is due to the stimulation of the plexus of Auerbach and structures peripheral to this. They seem to sensitize the motor autonomic system to normal stimuli. Morphine is used principally to relieve pain due to trauma. Its action on the peripheral endings of the autonomic nervous system is slight when given in therapeutic doses. (Opium, owing to its isoquinoline alkaloids, does have

a paralytic action on the peripheral endings of the autonomic nervous system.) Hence pitressin and prostigmine methylsulfate are compatible with morphine sulfate and may be used simultaneously in postoperative cases.

LIQUID SHAMPOO SOAP

To the Editor:—Will you please give me the ingredients of a good soap for shampooing the scalp. If no perfume is present, would it be possible to add something to give the shampoo mixture a faint perfume?

J. Wesley Bulmer, M.D., Glen Cove, N. Y.

ANSWER.—There are eight useful formulas for shampoos in the Recipe Book (American Pharmaceutical Association) including liquid and dry forms for dry and oily scalps. A representative "liquid shampoo soap" formula from this list is as follows:

Coconut oil	66 Gm.
Cottonseed oil	78 cc.
Stearic acid	36 Gm.
Potassium hydroxide	42 Gm.
Potassium carbonate	9 Gm.
Alcohol	42 cc.
Purified talc	10 Gm.

Distilled water, a sufficient quantity to make 1,000 cc.

Melt the stearic acid in the oils heated to about 82 C. Add the alkalis dissolved in 100 cc. of distilled water and then the alcohol; heat until saponified. When cool, add sufficient distilled water to make the product measure 1,000 cc. Add the talc and filter.

Any perfume desired may be added. Rose water, bay rum odor, oil of bergamot, oil of lavender, oil of eucalyptus, oil of dwarf pine needles and oil of rose geranium are recommended.

FATAL HEMORRHAGE FROM UMBILICAL CORD

To the Editor:—Recently I had a case of hemorrhage from the umbilical cord which terminated fatally. The hemorrhage occurred six hours after delivery and ligation of the cord, in an apparently normal full term infant weighing 7 pounds (3.2 Kg.). The hemorrhage was excessive but had ceased on my arrival. As I lacked facilities for proper emergency treatment, the infant died in about an hour. Inspection of the stump and ligature showed a perfect ligation and the bleeding had occurred past the ligature at the severed end of the cord. At the beginning of pregnancy the mother had a 4 plus blood Wassermann reaction and during the middle trimester she took twelve injections of nearsphenamine and twelve injections of a bismuth compound, no blood tests being taken after this and no cord Wassermann test being made at the time of delivery. From what I am able to find in the literature, hemorrhage from imperfect ligation of the cord seldom occurs this late after delivery unless there is some blood dyscrasia present. Could this have been due to congenital syphilis? I might add that resuscitation of the infant was normal and there were no signs of asphyxiation. Any information that you can give me with regard to the probable cause of this misfortune will be greatly appreciated.

M.D., Texas.

ANSWER.—Blood dyscrasias, congenital syphilis and hemorrhagic disease of the newborn (prolonged prothrombin time) may cause hemorrhage from the umbilical cord, but the bleeding is more prone to occur at the point of ligation (superimposed trauma) than at the severed end of the cord. However, any of these blood conditions sufficiently severe to cause a fatal hemorrhage from the cord would also cause severe bleeding from other areas, especially the mouth, gastrointestinal tract, nose and vagina. Bleeding from hemorrhagic disease usually does not appear for about twenty-four hours after birth. In short, a rapid severe or fatal hemorrhage from the severed end of the umbilical cord occurring six hours after labor in a normal appearing infant, without other external evidence of a hemorrhagic diathesis, would lead one to believe that the ligature had slipped or loosened in some way.

PROGNOSIS IN INFECTIOUS MONONUCLEOSIS

To the Editor:—I am writing to ask if you have any information as to the prognosis of infectious mononucleosis. I had this condition in a mild form several months ago and my policy with my health insurance was put in force with a waiver for any diseases of the white corpuscles. I am unable to find reference in any of the literature in which the disease, when ended, was not cured. Are there any cases on record of such a disease after the cure?

M.D., Ohio.

ANSWER.—The immediate prognosis of infectious mononucleosis is almost always good. A few cases have been reported with accompanying severe hepatitis or nephritis. Concerning the late prognosis, a mild anemia is common. Easy fatigability is frequently present for several months. The blood usually shows a lymphocytosis which may last as long as a year. No more serious complications are known. The only justification for a different prognosis is the possibility of a mistaken diagnosis. Leukemia can be confused with mononucleosis, although the differentiation usually is easily made and reasonably certain.

Medical Examinations and Licensure

COMING EXAMINATIONS

NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, June 1, page 2240.

STATE AND TERRITORIAL BOARDS

ALABAMA: Montgomery, June 18-20. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.
ALASKA: Juneau, Sept. 3. Sec., Dr. W. W. Council, Box 561, Juneau.

ARIZONA: Basic Science. Tucson, June 18. Sec., Dr. Robert L. Nugent, University of Arizona, Science Hall, Tucson. Medical. Phoenix, July 2-3. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

CALIFORNIA: Oral examination (required when reciprocity application is based on a state certificate or license issued ten or more years before filing application in California), Los Angeles, July 15. Written examination. San Francisco, June 24-27. Sec., Dr. Charles B. Pinkham, 1020 N St., Sacramento.

COLORADO: Denver, July 2-6. Applications must be on file not later than June 17. Sec., Dr. Harvey W. Snyder, 831 Republic Bldg., Denver.

CONNECTICUT: Written. Hartford, July 9-10. Endorsement. Hartford, July 23. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. Homeopathic. Derby, July 9-10. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

DELAWARE: Examination. Dover, July 9-11. Reciprocity. Dover, July 16. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA: Basic Science. Washington, Oct. 21-22. Sec., Dr. George C. Ruhlman, 203 District Bldg., Washington.

FLORIDA: Tampa, June 17-18. Sec., Dr. William M. Rowlett, Box 786, Tampa.

GEORGIA: Atlanta, June. Joint-Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta.

IDAHO: Boise, Oct. 1. Dir., Bureau of Occupational License, Mr. H. B. Whittlesey, 355 State Capitol Bldg., Boise.

ILLINOIS: Chicago, June 25-27. Superintendent of Registration, Mr. Lucien A. File, Springfield.

INDIANA: Indianapolis, June 18-20. Sec., Board of Medical Registration and Examination, Dr. J. W. Bowers, 301 State House, Indianapolis.

IOWA: Basic Science. Des Moines, July 9. Dir., Division of Licensure and Registration, Mr. H. W. Grete, Capitol Bldg., Des Moines.

KANSAS: Kansas City, June 18-19. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. Seventh St., Kansas City.

MAINE: Augusta, July 2-3. Sec., Dr. Adam P. Leighton, 192 State St., Portland.

MARYLAND: Medical. Baltimore, June 18-21. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. Homeopathic. Baltimore, June 18-19. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: Boston, July 9-11. Sec., Dr. Stephen Rushmore, 413-F State House, Boston.

MICHIGAN: Medical. Ann Arbor and Detroit, June 12-14. Sec., Dr. J. Earl McIntyre, 202-4 Hollister Bldg., Lansing. Basic Science. Detroit, June 28-29. Pres., Dr. R. C. Houston, East Lansing.

MINNESOTA: Minneapolis, June 18-20. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.

MISSISSIPPI: Jackson, June 26-27. Asst. Sec., Dr. R. N. Whitfield, Jackson.

MONTANA: Reciprocity. Helena, Sept. 30. Written. Helena, Oct. 1-2. Sec., Dr. S. A. Cooney, 216 Power Block, Helena.

NEVADA: Reciprocity with oral examination. Aug. 5. Sec., Dr. Fred M. Anderson, 215 N. Carson St., Carson City.

NEW JERSEY: Trenton, June 18-19. Sec., Dr. Earl S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: Santa Fe, Oct. 7-8. Sec., Dr. Le Grand Ward, 135 Sena Plaza, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, June 24-27. Chief, Bureau of Professional Examinations, Mr. Herbert J. Hamilton, 315 Education Building, Albany.

NORTH DAKOTA: Grand Forks, July 2-5. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OREGON: Medical. Portland, June 18-20. Sec., Dr. Joseph F. Wood, 509 Selling Bldg., Portland. Basic Science. July 6. Sec., State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

PENNSYLVANIA: Written. Philadelphia and Pittsburgh, July 9-11. Bridgside. Philadelphia, July 12-13. Dir., Bureau of Professional Licensing, Dr. James A. Newpher, 358 Education Bldg., Harrisburg.

PUERTO RICO: San Juan, Sept. 3. Sec., Dr. O. Costa Mandry, Box 3854, Santurce.

RHODE ISLAND: Providence, July 10-11. Sec., Division of Examination, Dr. Robert M. Lord, 366 State Office Bldg., Providence.

SOUTH CAROLINA: Columbia, June 25. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

SOUTH DAKOTA: Medical. Rapid City, July 16-17. Dir., Medical Licensure, Dr. J. F. D. Cook, Pierre. Basic Science. Written. Yankton, June 7-8. Endorsement. Watertown, June 22. Sec., Dr. Gregg M. Evans, Yankton.

TENNESSEE: Knoxville, Memphis and Nashville, June 14-15. Sec., Dr. H. W. Qualls, 130 Madison Ave., Memphis.

TEXAS: San Antonio, June 17-19. Sec., Dr. T. J. Crowe, 918-20 Mercantile Bldg., Dallas.

VERMONT: Burlington, June 11-13. Sec., Dr. W. Scott Nay, Underhill.

VIRGINIA: Richmond, June 18-20. Sec., Dr. J. W. Preston, 303½ Franklin Rd., Roanoke.

WASHINGTON: Basic Science. Seattle, July 11-12. Medical. Seattle, July 15-17. Sec., Department of Licenses, Mr. Nelson N. Vaughn, Olympia.

WEST VIRGINIA: Huntington, July 1-3. Sec., Public Health Council, Dr. Arthur E. McClue, State Capitol, Charleston.

WISCONSIN: Milwaukee, June 25-28. Sec., Dr. E. C. Murphy, 314 E. Grand Ave., Eau Claire.

Illinois January Examination

Mr. Lucien A. File, superintendent, Illinois Department of Registration and Education, reports the written examination (graduates of foreign schools given also a practical test) held at Chicago, Jan. 23-25, 1940. The examination covered ten subjects and included 100 questions. An average of 75 per cent was required to pass. Seventy-six candidates were examined, seventy-three of whom passed and three failed. Twenty-seven physicians were licensed by reciprocity and six physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Chicago Medical School.....	(1939)	78,	(1940) 82

Book Notices

Physiological Chemistry: A Text-Book for Students. By Albert P. Mathews, Ph.D., Andrew Carnegie Professor of Biochemistry, The University of Cincinnati, Cincinnati. Sixth edition. Cloth. Price, \$8. Pp. 1,488 with 113 illustrations. Baltimore: William Wood & Company, 1939.

Many physicians learned their biochemistry with the aid of earlier editions. The book has been extensively revised and rearranged. Much of the older material that has been retained has been rewritten. The laboratory section is omitted from the present edition. This book is not a brief manual but rather a collection of essays on the chemistry of the body. Many new items appear in the present edition. There are, for example, brief discussions of the pyranose formula of alpha-dextrose, the newer conceptions of the chemistry of the disaccharides and polysaccharides, and there is an entire chapter on glycolysis presented as only a master could do it. This is followed by a chapter on the carbohydrate metabolism of muscle and other tissues, a discussion of the metabolism of malignant cells and a chapter on the carbohydrates of the nucleus. Reference is made in the latter chapter to the work of Anderson and his associates on the chemistry of the tubercle bacillus. Each chapter contains a select bibliography of important papers and reviews. The chapters on fats and other lipids are not perhaps as complete as the corresponding chapters on carbohydrates, but this is probably the fault of the subject. The discussion of the sterols includes mention of the chemistry of cholesterol and related sterols of plant and animal tissues, the bile acids and the sex hormones. Bile is discussed in the section on digestion in the intestine, an arrangement which is somewhat unfortunate because the material on bile acids is discussed under sterols. The chapter on the viscosity of blood and on clotting is so complicated with terminology as to raise a question about its helpfulness to the beginning student. On the whole, however, the book can be commended. It emphasizes the rapid progress that has been made in biochemistry within recent years, a development which, the author points out, has made the material aspects of medicine more nearly an exact science.

Health Is Wealth. By Paul de Kruif. Cloth. Price, \$2. Pp. 246. New York: Harcourt, Brace & Company, 1940.

Here, in a small volume, Paul de Kruif has collected essays from the *Country Gentleman*, in which he campaigns for great expenditures in the field of public health. He favors a national health program, as who does not? He tells how Detroit fought tuberculosis. And then he tells how in December 1937 he and Surgeon-General Parran prepared a two page memorandum entitled "The Essentials of a National Health Program." This apparently was given to the President by Basil O'Connor of the National Foundation for Infantile Paralysis.

Then comes the story of the so-called National Health Conference, in which de Kruif recognizes the attempt of this conference to destroy public confidence in the medical profession, and he says "The net result of the conference was that the American people had less faith in the army that alone could fight for its higher level of health."

Next comes an account of a conference with Harry Hopkins and the preparation of a memorandum for him which he was to send to the President. Apparently nothing ever came of that. In his own words, de Kruif feels that he participated in the folly of a "ride on the Washington merry-go-round."

This chapter serves as the introduction to the essays which have appeared in the *Country Gentleman*, proposing de Kruif's own national health program. They are Human Erosion and Human Conservation.

Then de Kruif heard that Senator Wagner was going to introduce the Wagner Health Bill, and he arranged for an audience with Senator Wagner. He presented the Senator with copies of these articles, but apparently their effect, he says, was nil. The Wagner Health Bill itself he calls a "comedy of errors."

Next come three more essays from the *Country Gentleman*, endeavoring to give de Kruif and that periodical leadership in the organization of public health for the American people.

Then de Kruif tells how he, with certain Michigan physicians, arranged a conference with Dr. Thomas Parran with the idea of trying to get the government to withdraw its law suit against the American Medical Association and how the Michigan physicians prepared with de Kruif and Parran a national health program which they would approve. On Dec. 13, 1939, de Kruif had an opportunity to take to the President his ideas and those of his associates regarding the national health program. Apparently the President told him on that date of his own plan for building hospital health centers in rural regions and that it was quite possible to embark on such a plan as de Kruif presented. As every one knows, the hospital bill, conceived by the President and modified through numerous hearings before the Senate Subcommittee on Labor and Education, unanimously passed the United States Senate on May 30.

One finds a de Kruif with somewhat a new point of view in his concluding paragraphs—a de Kruif who is for the medical profession. Thus he says "The people can take courage from the stir in the ranks of their physicians. They have gone on record as being ready to take their place as pioneers in a nationwide advance toward a higher level of life which the people are already demanding. This advance will not be dictated by spurious political promises or by any well intentioned but unreliable spirit of do-gooding. It will be guided by the power of medical science."

Treatment by Manipulation. By H. Jackson Burrows, M.D., F.R.C.S., Assistant Orthopedic Surgeon, St. Bartholomew's Hospital, London, and W. D. Coltart, M.B., F.R.C.S., Chief Assistant, Orthopaedic Department, St. Bartholomew's Hospital. Published by "The Practitioner." Cloth. Price, 5s. Pp. 36, with 30 illustrations. London: Eyre & Spottiswoode, [n. d.].

This book is written by two orthopedic surgeons of considerable note and experience obviously in order to put manipulative surgery on a safe basis by means of proper selection of the cases and an understanding of the underlying principle, as is indicated in the preface to the book. It is called manipulative treatment rather than manipulative surgery and concerns itself with the passive movement of joints. To clarify the nomenclature the authors define sprain, acute or chronic, in reference to the joint only, while a strain is used in connection with particular components such as ligaments and, therefore, the sprain is the more general and the strain the more restricted term. It is gratifying to note that the principles of H. O. Thomas and his regard for the unsound joint is, at least by implication, recognized. From this point of view the short chapter on the selection of cases for manipulation is of particular interest. The authors consider the ideal case for manipulation the chronic sprain or strain resulting from chronic trauma with long continued mechanical strain, as for instance in scoliosis, lordosis and pes varus. Consequently they name inactive osteo-arthritis as one of the conditions suitable for manipulation, while tuberculous arthritis and any other form of arthritis, even though inactive, is definitely classed among the groups in which manipulation should not be applied. In only a few acute conditions is this treatment permissible. The method of manipulation and the details of technic are given special attention, particularly as far as the foot and ankle are concerned; also the treatment of the locked knee, the manipulation of the hip, especially in osteo-arthritic cases, and the manipulation of the spine. The methods are described in detail and in their different component manipulative steps. It is especially gratifying that the dangers of manipulation are emphasized, which lie first in the improper selection of the cases themselves and then from trauma by improper manipulation. The use of too much force is condemned, it being likely to lead to such complications as avulsion of the tibial tubercle, fracture of the upper end of the humerus, fracture of the metatarsal bones, or crush fracture of the vertebrae. Special caution is advocated in the treatment of osteoporosis from immobilization or from senility. The reader is warned in particular against such conditions as may lead to complications after manipulative maneuver. The book is well worth reading; it is written clearly and comprehensively and, above all things, it demonstrates the pathologic knowledge which is a welcome safeguard against the abuse of the method, which is so slow in being accepted by the medical profession having once fallen in disrepute by indiscriminate use.

Intelligence and Crime: A Study of Penitentiary and Reformatory Offenders. By Simon H. Tulchin. Cloth. Price, \$2. Pp. 166, with 13 illustrations. Chicago: University of Chicago Press, 1939.

Time was when the evils of mankind were explained, in large measure, by the boggy of feeble-mindedness. Poverty, unemployment and crime were directly related to intelligence defect. When systematic tests of intellectual capacity were applied in a routine way to some millions of American youths at the time of the draft for the World War, it was disconcerting to this theory to find that, according to the accepted standards at that time, one fourth of the young men accepted for the army were classifiable as feeble-minded. This caused enormous readjustments in the concepts of intelligence, feeble-mindedness and intelligence testing. It ought to have completely demolished the theory that crime was the result of stupidity, but it didn't.

Dr. Herman Adler, state criminologist of Illinois and director of the Institute for Juvenile Research, was anxious to substitute facts for theories regarding this question, although he himself was convinced that it was absurd to relate crime directly to feeble-mindedness. In one brief survey he showed that the intelligence capacity of the guards of one of the Illinois prisons was distinctly below that of the criminals that were guarded; but he sought to have the matter thoroughly investigated, and a number of psychologists—E. K. Wickman, John Metcalf and the author of this book—set to work and surveyed the population of the penal and correctional institutions in the state. Following the survey, during the seven years between 1920 and 1927, Tulchin examined more than 10,000 prisoners in three penal institutions in the state of Illinois.

Now, twelve years after the survey was completed, the results of these studies have been carefully tabulated, correlated and analyzed. In this small book, more data pertaining to the relation of intelligence to crime are assembled than in any other existing study. In addition, intelligence is considered in relation to nativity, race, recidivism, age, height, weight, educational record, marital status, employment status, and religion of the criminals.

As compared with the army experience, it is quite clear that feeble-mindedness is no more characteristic of criminals at large than it is of noncriminal youth. For example, 23.4 per cent of the population of the penitentiary were classifiable as inferior; but 25.9 per cent of the United States Army recruits were thus classifiable. Of the penitentiary population, 11.8 per cent was classifiable as superior; of the army, 10.6 per cent. In the reformatory, only 15 per cent of the men were rated as inferior and 13 per cent as superior. But while feeble-mindedness cannot be said to cause or be related directly to crime, Dr. Tulchin's figures do show a definite relationship between certain types of crime and the intelligence of the offender. Thus, those who commit sex crimes were regularly the most stupid, those guilty of fraud regularly the most intelligent.

Many other conclusions of a higher degree of differentiation are drawn by the author on the basis of his carefully studied statistics. The book is a fundamental contribution to fact finding in a field where guesswork and small sampling have long been the rule. The inspiration of Herman Adler and the indefatigability of Simon Tulchin deserve the gratitude of scientific workers in psychiatry, psychology and criminology for this unassuming but very significant study.

Ways to Community Health Education. By Ira T. Hilscock, Professor of Public Health, Yale University School of Medicine. With the collaboration of Mary P. Connolly, Marjorie Delavan, Raymond S. Patterson and William H. F. Warthen. Cloth. Price, \$3. Pp. 306, with illustrations. New York: Commonwealth Fund; London: Oxford University Press, 1939.

This book, an important contribution to the literature of health education, is an illustrated manual—illustrated with actual examples of successful devices used in health education by all sorts of agencies engaged in this activity. Medical societies, dental societies, health departments, professional societies and voluntary health agencies have all contributed to this volume. Carefully edited by five prominent health educators in various fields, liberally documented and replete with ideas, practical advice and examples of effective use of the several mediums and methods in health education, it should find a permanent place on the desk of every person interested in health education, in health administration or in any activity in which communication with the public is essential. The book deals first with the

mediums: radio, platform addresses, printed matter and displays. It then gives examples of effective use of these mediums in connection with diphtheria and smallpox control, infant welfare, sanitation, tuberculosis and syphilis control, and other applications to the usual community health program. The textual matter not only is packed with useful information but is distinctly readable.

The principal feature of the book is the illustrative material. Color plates, photographs, reduced facsimiles of printed matter and type samples are used effectively. They are gathered from health departments large and small, medical societies and academies of medicine, voluntary health agencies and governmental departments. They illustrate what can be done by showing what has been done and how it was done.

Heavy emphasis is placed throughout on the importance of the medical profession in health education, not only by frequently repeated advice about medical cooperation, but by citing examples and printing illustrations of how medical societies are regularly contributing to health education projects.

Evans' Recent Advances in Physiology. Revised by W. H. Newton, M.D., M.Sc., Reader in Physiology, University of London, University College, London. Sixth edition. Cloth. Price, \$5. Pp. 490, with 109 illustrations. Philadelphia: P. Blakiston's Son & Co., Inc., 1939.

This useful book is composed of twelve essays on the present status of various topics in physiology. As in the previous editions there are discussions of the sex hormones, the mechanism of oxygen supply to the fetus, the transport of carbon dioxide in the blood, the metabolism of cardiac muscle, the secretion of urine, the nervous control of micturition, chemical transmission at nerve endings, and the spinal reflex. New chapters have been included on some aspects of the physiology of bone, the Carrel-Lindbergh perfusion apparatus, certain problems of carbohydrate metabolism, and the cortical control of muscular movement. The portion of the book which has been carried over from the previous edition has been revised and rearranged. The book is well illustrated, each chapter contains a select bibliography, and there is a suitable index. The volume may be considered as an advanced textbook on certain phases of physiology. There are a host of unsolved problems in each chapter. The book will be of great value to the serious student of physiology.

A Textbook of Medicine. By Various Authors. Edited by J. J. Conybeare, M.C., D.M., F.R.C.P., Physician to Guy's Hospital, London. Fourth edition. Cloth. Price, \$6.75. Pp. 1,112, with 50 illustrations. Baltimore: William Wood & Company, 1939.

The 1939 edition offers to the student of medicine in essence an encyclopedia covering the entire field of medicine with extensive sections on neurology and psychiatry and a briefer section on dermatology. The work is popular in England, comparable to Osler or Cecil here, is reminiscent of Osler and McCrae in both organization and style and is written in an easily readable and understandable fashion. Noteworthy are the thorough manner in which each disease is discussed from the standpoint of symptomatology and diagnosis, the addition of pediatric aspects to discussions on the various infectious diseases, together with a chapter on gastrointestinal disorders of infancy, and a brief but adequate description of laboratory-clinical procedures when indicated as diagnostic measures. The section on neurology is probably sufficient to handle ordinary medical school needs in that subject, that on psychiatry is designed to give the student a familiarity with the subject. Common skin diseases are well handled in forty-eight pages on dermatology. Medicolegal aspects and instruction on proper insurance examinations are informatively discussed. Disadvantages lie in unfamiliar terminology as pertains to American students, and in the treatment of therapeutics. The names of proprietary preparations will not be recognized. Pharmaceutical nomenclature is confusing and dosages are entirely in the apothecary system. The most glaring fault lies in the unmodernized chapter on pneumonia, omitting entirely the all important strides that have been made in the last five years in the treatment of this condition. The old classification of three types and a fourth group is still adhered to. Serum is only briefly mentioned to be used only in types I and II. Sulfapyridine is not included. The important addition of sulfanilamide to our therapeutic armamentarium is almost entirely missed, being mentioned only briefly in the treatment of streptococcal septicemia and then in inadequate dosage. Old

traditional therapeutic measures, such as the use of whisky in pneumonia and frequent spinal drainages in epidemic meningitis, are still laid down perhaps too dogmatically as effective treatment adjuncts. We probably shall not agree with a course of treatment of early acquired syphilis that includes frequent interspersions of rest periods.

Injection Treatment of Hernia, Hydrocele, Ganglion, Hemorrhoids, Prostate Gland, Angioma, Varicocele, Varicose Veins, Bursae, and Joints. By Penn Riddle, B.S., M.D., F.A.C.S., Assistant Professor of Clinical and Operative Surgery, Baylor University College of Medicine, Dallas. Cloth. Price, \$5.50. Pp. 290, with 153 illustrations. Philadelphia & London: W. B. Saunders Company, 1940.

The increased popularity of the injection method of treatment is responsible for this authoritative work. Experience of many reliable workers showed that skepticism as to the safety and value of this method has been founded on theoretical misconceptions. On the other hand, the recent wave of enthusiasm over the injection method has created the impression that this treatment is not only a panacea for all types of hernias and varicose veins but also a simple office procedure which will save the patient time and money. The consensus at the present time is that the injection method has its field of usefulness, good results depending on an accurate differential diagnosis of the type of hernia, good judgment in selection of suitable cases, a thorough knowledge of the regional anatomy, proper technic of injection and, last but not least, a familiarity with fitting scientifically correct trusses. Too strong emphasis cannot be placed on the limitation of this method of treatment to men especially qualified in its use because there are definite inherent dangers in the procedure. The same remarks are applicable to the injection treatment of other conditions amenable to such therapy. Those wishing to employ this method are given in the book an excellent opportunity to acquaint themselves with the necessary details of treatment not only of hernias but also of varicose veins, hemorrhoids, hydrocele, varicocele, ganglion, angioma, bursae, joints and the prostate gland. The subject is covered completely and in a concise manner, the printing and illustrations are of a high quality. Only one omission has been noticed: among contraindications to injections of hernia, superficial cutaneous infections and the sliding hernia have not been mentioned. The book will undoubtedly receive a warm welcome from all interested in the subject.

Khimicheskaya priroda nervnogo vozbuзhdeniya v organizme cheloveka. [By] Prof. D. E. Alpern. [Nature chimique de l'excitation nerveuse dans l'organisme de l'homme.] Paper. Price, 7 rubles. Pp. 232, with 59 illustrations. Kharkov: Edition de l'Institut de médecine expérimentale d'Ukraine, 1939.

The author accepts as proved the existence in the human organism of neurohumoral substances, chemical factories of nervous stimulation. Sympathin and vagus substance have been demonstrated in experiment by many investigators. These substances are demonstrable in normal states when the vegetative nervous system is stimulated or when one of its functions is interfered with. The oculocardiac phenomenon of Aschner offers a convincing illustration. The presence of the vagus substance can be demonstrated in the blood when this phenomenon is positive. The classic experiments of Loewi and the contributions of Dale and Cannon demonstrated that formation of chemical substances accompanies the reflex activity of the vegetative nervous system under normal conditions. Some of these substances may act as vasodilators or as vasoconstrictors and cause an imbalance in a given vascular area. In the course of a number of years of study of tissue metabolism the author and his co-workers at the Ukrainian Institute of Experimental Medicine demonstrated the presence of chemical agents in a number of diseases in the pathogenesis of which alterations in the function of the vegetative nervous system play a part, such as gastric ulcer, bronchial asthma, spastic colitis and spontaneous gangrene. The substances are formed not only in the peripheral tissues but in the central nervous system as well. Thus acetylcholine-like substance has been found in the cerebrospinal fluid of man in the presence of a positive oculocardiac reflex and in an epileptic syndrome. Chemical substances are liberated as a result of the activity of the nervous system. In gastric ulcer and in spastic colitis, increased liberation of acetylcholine takes place in the gastric or the intestinal wall. The author further maintains the existence of synergism between

the various chemical mediators and regulators. The existence of antagonistic mechanism can be likewise demonstrated. Such a counterregulator in the presence of accumulation of acetylcholine is cholinesterase, found in all the tissues of the human organism. The presence of acetylcholine can be demonstrated only after a preliminary introduction into the organism of physostigmine, which paralyzes the action of cholinesterase. The presence of the vagus substance stimulates the liberation of other antagonists such as epinephrine and sympathin. These investigations suggest the possibility of a new biologic method for the evaluation of the functional state of the vegetative nervous system. A consideration of the antagonistic factors permits a clearer understanding of the mechanism of a disease state and offers an opportunity for the study of the pathogenesis of the diseases of the vegetative nervous system. An extensive bibliography on this subject is appended as well as a summary in French.

The Therapeutics of Internal Diseases. Supervising Editor: George Blumer, M.A., M.D., David P. Smith Clinical Professor of Medicine, Yale University School of Medicine, New Haven. Associate Editor: Albert J. Sullivan, M.D., Chief Medical Officer, Gallinger Municipal Hospital, Washington, D. C. In Two Volumes. Cloth. Price, \$20 per set. Pp. 872, with 1,042 illustrations. New York & London: D. Appleton-Century Company, Inc., 1940.

The introduction to these volumes by Dr. George Blumer should be made required reading for every medical student. He makes it clear that the chief duty of the physician is to treat the patient, but he also makes clear that an accurate diagnosis should, wherever possible, precede treatment. He points out that the physician is treating not the disease or the diseased organ but the patient. "The plan of treatment should be as simple as possible," he says, "and it is well to put down in black and white directions as to the extent of rest or exercise, the character and amount of food and fluids, means of obtaining sleep, the regulation of the emunctories and, of course, the dosage and times of administration of medicines." Interesting also is his comment regarding proprietary remedies. He says:

If the practitioner of medicine is to develop therapeutic wisdom it is necessary that he should be aware of the pitfalls which beset the uncritical therapist and that he should develop a questioning attitude of mind. It is obvious from even a superficial perusal of medical literature that every promising new remedy goes through three stages. After its introduction a stage of reaction during which numerous articles appear calling attention to its drawbacks and unpleasant side-effects, and finally a time comes when a true estimate of its value has been reached (stage of balance). In order to estimate the value of therapeutic agents it is necessary for the practitioner to adopt methods of appraisal and to view the whole subject with a scientific attitude of mind. Too often physicians form their estimation of the value of treatment on impressions, on the statements of their powered detail men from drug houses, or on ill digested opinions of their colleagues; too often they are practicing a generation after graduation on the therapeutic ideas they learned in medical school.

These two volumes are of the symposium type, the first volume taking up methods of therapy, including not only nutrition and dietetics but also special headings such as electricity, radiotherapy, occupational therapy, serum therapy, vaccines, bacteriophage and various methods of administering therapy, including intravenous, intramuscular and spinal technics. The second volume then proceeds with pharmacology and uses of drugs, toxicology, and finally the methods of treatment in the various infectious diseases.

The contributors have all been selected for their prominence in the fields which they discuss and for the fact that all of them have contributed at one time or another to the scientific literature in those fields. The work is well edited, systematic in presentation, and up to date in its bibliography, and altogether a most useful contribution.

Diagnostic Signs, Reflexes and Syndromes Standardized. By Wm. Egbert Robertson, M.D., F.A.C.P., Visiting Physician, Medical Division, Philadelphia General Hospital, Philadelphia, and Harold F. Robertson, B.S., M.D., F.A.C.P., Instructor in Medicine, University of Pennsylvania, Philadelphia. Fabrikoid. Price, \$3.50. Pp. 309. Philadelphia: F. A. Davis Company, 1939.

This is essentially a dictionary of all the usual signs and reflexes, many of them eponyms. It is a work of reference rather than one which would have any value for consecutive study. The work is obviously not all inclusive, and it is doubtful that any such book could be. The work should be of great aid to record librarians who must occasionally transfer eponymic designations into scientific nomenclature.

Biological Products. By Louis Gershenfeld, P.D., B.Sc., Ph.M., Professor of Bacteriology and Hygiene, and Director of the Bacteriological and Clinical Chemistry Laboratories at the Philadelphia College of Pharmacy and Science, Philadelphia. Cloth. Price, \$4. Pp. 236, with illustrations. New York: Romaine Pierson Publishers, Inc., 1939.

This volume contains various series on biologic products heretofore published in various periodicals, including the source, preparation and manufacture of products. Furthermore, it embodies the composition, therapeutic and prophylactic uses and methods of standardization. The book should prove useful to those working in such a field, particularly allied to public health.

Faiths That Healed. By Ralph H. Major, M.D. Cloth. Price, \$3. Pp. 290, with 30 illustrations. New York & London: D. Appleton-Century Company, Incorporated, 1940.

The relationship between faith and healing has given rise to various sects and beliefs associated with the curing of disease. Dr. Ralph Major has collected many of these and gives their histories and background. Here is an analysis of the growth of Christian science, of the background of Lourdes, the rise of witchcraft and many a similar subject. There are references to Mesmer, Quimby, Paracelsus and Zeileis. Strangely, the name of Coué does not appear in the index. Those who wish to trace the evolution of those who have exploited the relationship of body to mind will find in Dr. Major's book a well written account which will inspire thought and reflection.

Physicians' Fare. By C. G. Learoyd. Cloth. Price, \$2. Pp. 302. New York: Longmans, Green & Co.; London: Edward Arnold & Co., 1939.

This is a collection of distinctly medical stories by a British physician who is, at the same time, a competent writer of short stories. Some of these stories have appeared in *Blackwood's Magazine* and in the *Evening Standard*, but most of them have appeared during the last three years in the *St. Thomas's Hospital Gazette*. They vary from the macabre as "A Nice Quiet Locum-Tenency" to the mysterious and the humorous. Particularly interesting are those which are a satire on psychoanalysis.

The Waiting Room. By Helen Irving Oehler. Cloth. Price, \$1. Pp. 77. New York: Fortune's, Publishers, 1940.

The author—a nurse—has collected reminiscences, anecdotes and personal observations of medicine and its practice. She talks about her operation and her experiences. She wants a doctor for the future who will be a specialist with a general practitioner's soul, and she knows that she does not want socialized medicine.

The Medical Record Visiting List or Physicians' Diary for 1940. Revised. Cloth. Price, \$1.75 for 30 patients per week; \$2 for 60 patients per week; \$2.50 for 90 patients per week. No pagination. Baltimore: William Wood & Company, [n.d.].

For many years this has been a standard item whose annual rebirth merely needs recording. The present volume follows quite definitely the pattern of all previous issues, even so far as to continue the old lists of poisons, but fails to include innumerable new substances. Perhaps the book would be just as good with merely the blank pages suitable for records and the obstetric calendar and without the other obsolete contents.

The Medical Career and Other Papers. By Harvey Cushing. Cloth. Price, \$2.50. Pp. 302. Boston: Little, Brown & Company, 1940.

Some of the best papers of Harvey Cushing are here collected, divided into those which deal with medical education and the social aspects of medical service and those which are excellent biographies. The notes concerning William Thomas Councilman and the Mayo Brothers are of current interest. Most significant of all these essays is the one called "Medicine at the Crossroads," first published in *THE JOURNAL*. The entire collection is as well written, as inspiring, a group of essays as could well be accredited to any one physician.

The New York Hospital Handbook of Applied Nutrition. Cloth. Price, \$2. Pp. 136. New York, 1939.

This is a compilation of diets used in the New York Hospital and as such is a practical guide to routines which are common in many leading institutions.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Injury or Severance of Facial Nerve During Radical Mastoidectomy.—The defendant physician, an otologist or specialist in diseases of the ear, was employed by the plaintiff to treat a condition of her right ear. He found her suffering from a chronic infection of that ear and mastoiditis, an infection of the mastoid process of the temporal bone. To eradicate the infection the defendant, with the assistance of another otologist called in consultation by the patient, performed a radical mastoidectomy under ether anesthesia. After the operation a facial paralysis on the right side developed. While the patient was aware when she regained consciousness that her face felt "tight or drawn," she did not notice the paralysis until the third postoperative day when she looked into a mirror. The defendant continued to treat her until eight months later when he referred her to Dr. Semmes, a specialist in surgery of the nerves, and another otologist. The latter physicians performed an exploratory operation and found that the plaintiff's right facial nerve had been severed where it coursed through the facial canal in the region of the mastoid. The ear ceased to discharge pus three weeks later, and thereafter these two physicians performed a second operation and inserted a nerve graft. The facial paralysis persisted and the patient brought suit for malpractice against the defendant physician. From a judgment of the trial court directing a verdict in favor of the defendant, the plaintiff appealed to the court of appeals of Tennessee, western section.

The plaintiff contended that the defendant physician had performed the mastoidectomy in an unskillful and negligent manner, causing severance of the facial nerve and paralysis of the right side of her face; that he was negligent in not promptly disclosing to her the nature and cause of the paralysis and in assuring her that it was only a temporary condition, thus causing her to refrain from consulting other physicians until it was too late to correct the condition, and that because of his negligence the paralysis was rendered permanent. She testified that prior to the operation the defendant assured her that the procedure was comparatively simple and that the only risks involved were those of losing her hearing, which was already impaired, and the danger incident to taking a general anesthetic. According to her testimony, the defendant also assured her after the operation, on being asked concerning the facial paralysis, that the condition was temporary. On one occasion, she said, he informed her that it had been caused by iodine getting under the ether cone and on another occasion he told her that something was probably pressing against her facial nerve.

The medical testimony, said the court of appeals, was in accord that a radical mastoidectomy is a delicate operation requiring great skill and that the operation performed by the defendant had been skilfully done, except that the facial nerve, which is located in the immediate region of the mastoid, had been injured, probably cut. Dr. Semmes, the neurosurgeon, testified that paralysis of the facial nerve can be caused by swelling, inflammation or injury of the nerve. It was his opinion that in the instant case the facial nerve had probably been cut or so damaged by trauma as to cause it to slough. There was also unconflicting medical testimony that mastoiditis has a tendency to cause destruction of bone in the region of the mastoid process and that it was necessary for the defendant, in performing a radical mastoidectomy, to remove diseased bone in that region and to hollow out the entire mastoid region completely to relieve it of infection. Dr. Semmes testified, and his testimony was not controverted, that when the facial nerve is severed in the course of an operation there are two methods of repair available: (1) by direct suturing of the ends of the severed nerve if they can be approximated and (2) by grafting a section of nerve between the severed ends of the facial nerve when those ends cannot be brought together. He stated that at the time he performed the nerve graft there was a space of about one-half inch (1.25 cm.) between the severed ends of the

facial nerve. In his opinion, because of the location of the nerve in the facial canal, very little retraction of the ends of the nerve would have resulted from the time of the mastoidectomy to the time he was called in on the case. In the instant case the facial nerve could not be repaired by direct suture, because the severed ends could not be approximated, and so a nerve graft was indicated. He further testified that when a nerve is severed it is better to suture it at once, if that is possible, but if a graft is indicated it is better to wait until the infection has disappeared entirely. It was shown that after an operation for mastoiditis infection usually persists for some considerable time. In the judgment of the court, the effect of Dr. Semmes's testimony was that, even if a repair of the severed nerve had been attempted promptly after the mastoidectomy, a nerve graft would have been the only method of repair that could have been used, and it would not have been good surgery to do the grafting until the infection had disappeared.

In view of this unconflicting medical testimony, the court could not agree with the plaintiff's contention that the facial nerve was not located within the region of the mastoid but was outside of the field of operation and that therefore the injury to the facial nerve in the course of the operation performed by the defendant brought the case within the doctrine of *res ipsa loquitur*. That doctrine, said the court, is applicable where the cause of action is based exclusively on some negligent act of a physician which could not ordinarily result from a careful or skilful treatment or operation. In the instant case, however, medical testimony showed that the facial nerve, where it was injured by the operation for mastoiditis and that in this type of operation there is always danger of injuring that nerve. Also, continued the court, uncontroverted expert medical testimony, which was properly admitted by the trial court and was not an invasion of the province of the jury, showed that it is possible for a surgeon performing a radical mastoidectomy to injure or sever the facial nerve even when he performs that operation with the highest degree of care and skill.

It was the opinion of the court that the defendant's failure to use certain other instruments recognized by the medical profession did not raise, as the plaintiff contended, a presumption of negligence. Where it is shown, said the court, as the evidence in the instant case showed, that the instruments used in an operation are of a type approved for performing such an operation and the surgeon's technic is up to the recognized standard of efficiency and skill, failure to use other approved instruments does not constitute negligence.

In the judgment of the court, the trial court correctly held that expert medical testimony must be controlling in this case since the only questions involved were those of science. The court concluded, therefore, that the evidence in the case did not warrant the submission of the issues to the jury because any verdict by it would essentially have been based on pure speculation. Accordingly, the trial court's judgment of non-suit was affirmed.—*Calhoun v. Fraser (Tenn.)*, 126 S. W. (2d) 381.

Injury to Eye Due to Hair Dye.—The plaintiff sustained injury to one of her eyes following the application of a dye, apparently a liquid for dyeing hair, which had been placed on the market by the defendant laboratories. She and her husband sued the laboratories and from an adverse judgment the plaintiffs appealed to the supreme court of New York, appellate division. It was actionable negligence, said the supreme court, for the defendants to put on the market a dangerous and poisonous dye. To recover it was not necessary that the plaintiffs prove that the defendants had actually manufactured and distributed the dye. The court held, therefore, that the trial court had erred when it refused to instruct the jury that, if the evidence established that the liquid was dangerous and poisonous and that injury to the plaintiff's eye followed contact with it, it might be inferred, without further evidence as to how the particular bottle happened to contain a dangerous and poisonous substance, that such a condition could not have arisen without fault on the part of the employees of the defendants. Of course, if prior to the application of the dye the plaintiff as a patron was apprised, which was not shown by the evidence, that the liquid was

dangerous and poisonous, then she would have assumed the risk involved. In the judgment of the court it was immaterial that the defendants had informed a so-called beautician that the dye contained a metallic salt and had also advised that patrons be instructed to keep their eyes closed during its application. The judgment of the trial court in favor of the defendant was therefore reversed and a new trial granted.—*Petzold et al. v. Rose Laboratories, Inc., et al. (N. Y.)*, 11 N. Y. S. (2d) 565.

Dental Practice Acts: "License" and "Certificate" Synonymous.—The defendant was convicted of practicing dentistry without a "license" in violation of the dental practice act of Alabama, which provides: "Any person who practices dentistry in this state without having received a certificate as therein provided shall be guilty of a misdemeanor." He appealed to the court of appeals of Alabama and contended that the trial court had erred in overruling his demurrer to its indictment which, as he claimed, improperly charged that he had engaged in the practice of dentistry without a "license" instead of charging that he had engaged in such activities without a "certificate." Since the dental practice act used the words "license" and "certificate" interchangeably, in the judgment of the court of appeals the charge that the defendant "did practice or engage in the business of dentistry without a license contrary to law" was sufficient to put the defendant on notice that he had engaged in the practice of dentistry without having complied with the requirements of the dental practice act. The court of appeals, therefore, affirmed the judgment of conviction. The defendant's petition for a writ of certiorari to review the decision of the court of appeals was denied by the Supreme Court of Alabama.—*Dye v. State (Ala.)*, 188 So. 74; 188 So. 15.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1930 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Comparison of Prophylactic Antirachitic Effects of 135 and 200 Unit Irradiated Evaporated Milks, 200 Unit Irradiated Fresh Milk and Human and Nonirradiated Evaporated Milk Fortified with 800 to 1,000 Units of Vitamin D as Viosterol. Edith C. Robinson, St. Louis.—p. 816.

Tetanus in Childhood.—Dietrich reviews twenty-eight cases of tetanus treated at the Children's Hospital from 1921 to 1939. Twelve of fifteen children treated between 1921 and 1932 died, but only one of the thirteen treated from 1933 to 1939 died. Most of the deaths in the first group and the only death in the second group occurred as a direct result of treatment. The improved rate of mortality in the second group was due to the more judicious use of serum and to the increasing dependence on sedatives. Refinement of serums in the last few years probably aided in reducing the number of severe reactions. A few of the children in the second group had severe reactions to serum but survived. One thousand five hundred units of antitoxin offers insufficient protection to the child with a compound fracture, but it apparently protects one with a minor wound. In the last eighteen years no child who received antitoxin for such a wound has been admitted to the hospital with tetanus. Most cases of tetanus seen in a children's hospital arise from wounds of such a trivial nature that the physician and often the mother are not consulted by the child. The further reduction of morbidity from tetanus must lie in the active immunization with tetanus toxoid of large groups of children. Every child who died had an extremely severe reaction immediately following serum intravenously or intrathecally. The immediate lethal factor was demonstrated in six necropsies to be medullary edema. Because

of the rapid reaction following intravenous or intrathecal administration of serum, it seems reasonable to assume that the edema was the result of some reaction to the serum. In four cases in which lumbar punctures were done before and from eight to twenty hours after the introduction of tetanus antitoxin into the subarachnoid space an acute inflammatory process was evident. The second group of thirteen cases emphasizes the relation between the route by which the serum is administered and the severity of reaction. The four patients given serum intrathecally and intravenously had severe reactions. They differed from the fatal ones only in a quantitative degree. Four patients were given intramuscular injections and they were the only ones not to show untoward reactions. Because time is an important factor, the intravenous is theoretically the ideal route for the administration of at least the first dose. It is better to assume the risk of slow effect and to give the antitoxin intramuscularly. One may give one dose of antitoxin and epinephrine intravenously and follow it by intramuscular administrations to maintain the concentration in the blood. An untried plan which may prove to be ideal, suggested by Hyland, is to obtain human tetanus antitoxin by immunizing donors with tetanus toxoid. One could give at first a single dose of human serum intravenously without fear of an untoward reaction. The concentration of antitoxin in the blood could be maintained safely by daily doses of orthodox tetanus antitoxin intramuscularly. Sedatives are of great value and are indicated before other therapeutic or diagnostic procedures are undertaken. The three important phases in the treatment are to spare the patient with adequate sedation and quiet surroundings, to provide a continuous but moderate supply of antitoxin to neutralize (preferably by intramuscular injection) any new toxin liberated and to supply reasonable amounts of fluid and nourishment during the first three to seven critical days. Seconal (sodium propylmethylcarbonylallylbarbiturate) for sedation has proved almost ideal in the three cases in which the author has used it.

Obesity in Childhood.—Bruch obtained information regarding the eating habits of 136 obese children from 2 to 13 years of age. The parents of 80 per cent of the children recognized that the food intake was larger than average. In the remaining 20 per cent it was described as normal or small, but the "normal" and "small" were not so much an estimate of the child's food intake as of the parents' exaggerated expectations as to what the children should eat. In all cases food intake was in better agreement with the rate of gain in weight than with the excess in weight. A preponderance of starchy food was shown. The emotional development of forty of the patients and their mothers was studied. The majority of the children had been exposed to prolonged overprotection. They exhibited signs of immature behavior not only in their eating habits but in other respects. For many obese children deprived of other outlets and satisfying contacts, the intake of food had gained an inordinate importance. Prolonged overprotection of 35 per cent of the children was partly explained by the fact that they were only children, and another 35 per cent were youngest children. In many instances a great difference in age or the death of another sibling accentuated the peculiarity of the family position. Increased desire for food frequently became manifest only after some upsetting experience: fear for the integrity of the body and of suppressed aggression. The maternal attitude was sometimes shaped by deprivation during her own childhood and rejection of the child. In all instances the offering and receiving of food represented an important emotional tie in the mother-child relation. Only 5.6 per cent of the patients came spontaneously for treatment of obesity. This group showed the best degree of cooperation. The poorest cooperation was shown by the children who came to the clinic with the definite expectation of receiving glandular injections for correction of the excess weight. A hypothesis is advanced that emotional experiences call into play functional disturbances of the hypothalamus which may be of importance in the large group of obese patients in whom no organic lesion can be detected.

Giardiasis.—Véghelyi studied the digestion and intestinal absorption of seventeen children infected with *Giardia*. Apart from the infection with *Giardia lamblia* no pathologic condition was found which could be held responsible for the symptoms, the anemia and the retarded development. Fat absorption was

markedly defective and only a small portion of the normal urinary pigment was excreted. The condition was attributed to the mechanical effect of the parasites covering the wall of the intestine and rendering it impermeable. The parasites almost cover the active surface of the intestine. The degree of impairment is probably proportional to the area of intestinal surface rendered inactive. If this surface is small, capacity for absorption may remain intact and no symptoms will arise. This may explain the fact that "healthy carriers" without symptoms are not rare. Infection may be severe enough to paralyze extensive intestinal surfaces and lead to a condition similar to atrophy from inanition. This state is further aggravated by the fact that, besides foodstuffs, other important substances, such as bile and vitamins, are not absorbed and by the fact that a great part of the available supply of calcium and magnesium is expended in binding the excess of free fatty acid. In this respect the condition resembles celiac disease. Twelve of the seventeen children were treated, but systematic reexaminations of only eight could be made. Acetarsone and acridine compounds were administered and no special diet. All eight were freed from the parasites, recovery taking place in from three and a half to seven weeks. Treatment was continued until cysts could no longer be detected in the stools after a provocative test with sodium sulfate on three consecutive days. Normal absorption was demonstrated after the treatment. Utilization of the fat returned to normal, the urinary pigment appeared in normal amounts, the anemia improved and body growth proceeded promptly. Improvement was gradual and was manifest on the fourth or fifth day after treatment was begun.

Pelvic Endometriosis.—Slow growth, limited invasive properties and dependence on ovarian stimulation characterize endometriosis as a benign process despite its widespread dissemination. No other nonmalignant growth is so capable of such widespread involvement as is endometriosis. Payne found, in a study of 307 patients with this condition, 343 major lesions and innumerable minor lesions not considered in the analysis. The ovaries were the most frequent sites of endometriosis (64 per cent). Unilateral ovarian involvement constituted 36 per cent of the lesions and bilateral 28 per cent. Widespread infiltration of the culdesac constituted 25 per cent of the massive lesions. This was frequently associated with endometriosis

in other localizations, particularly the ovaries. The process extended into the rectovaginal septum producing a nodular infiltration resembling a malignant condition of the rectum. Rectal digital and proctoscopic examinations clarify the diagnosis, as endometriosis does not infiltrate the rectal mucous membrane as does a malignant growth. The fallopian tubes were moderately frequent sites of endometriosis, 3.2 per cent, and endometriomas of tubal stumps accounted for 1.1 per cent of them. Other areas of implantation were the external surface of the uterus, the broad ligament, the umbilicus, the cervix and a laparotomy scar, a bladder and an appendix. Any portion of the intestinal tract in or near the pelvic cavity may be involved. A characteristic feature of endometriosis is its association with other pelvic pathologic changes or disorders which overshadow both the symptoms and signs of the adenomas. Fifty-nine patients presented endometriosis alone, while the remaining 248 patients had a total of 367 complicating conditions. The following may be mentioned in order of frequency: uterine myomas, fibroids, perisalpingitis or perioophoritis, uterine retrodisplacement, cervical stenosis and ovarian neoplasms. Endometriosis is a disease of the menstrual life, with an incidence of approximately 80 per cent between the fourth and sixth decades. Its chief symptoms are those of local pain, alterations in the menstrual and reproductive processes and dysfunction of the contiguous organs. Treatment, routine observation, surgical intervention or irradiation are determined by the severity of symptoms, the patient's age and the operative removability of the major lesions. Conservatism, particularly in young patients, is justified by the results: From 90 to 95 per cent were completely or partially relieved of symptoms, 8 per cent required further treatment and 9 per cent had subsequent pregnancies.

Heart Disease and Pregnancy.—Jensen and his associates studied 108 obstetric patients with cardiovascular disease. The study aimed to determine to what extent care extended to this class of patient has affected maternal and infant death rates. Ninety-nine of the 108 women had rheumatic, seven congenital and two syphilitic heart disease. The patients with rheumatic heart disease presented various valvular lesions. Eight women died of heart disease. Of these cases only two belong to the regular antepartum series. There were no deaths among the patients with organic heart disease who followed instructions and received adequate antepartum care from the beginning of pregnancy. Heart disease has been an important cause of death in St. Louis Maternity Hospital. Of forty-four maternal deaths, six could be traced directly to valvular disease of the heart or its immediate complications. The six died within six months of delivery. The fact that no cardiac deaths occurred in properly managed pregnant women leads the authors to believe that while some cardiac patients should not become pregnant or should have their pregnancies interrupted if they do, the majority can be carried successfully to term if given adequate antepartum care. The treatment of these cases has been conducted along generally accepted lines.

Preservation and Use of Placental Blood.—Fine and his collaborators conclude from their studies that placental blood is suitable for transfusion in adults provided it can be collected sterily and in sufficient quantities and can be satisfactorily preserved. Placental blood could apparently be collected and preserved sterily, but the subsequent transfusions were accompanied by a high percentage of reactions. A comparative study of different preservative solutions suggested that 1.5 per cent of sodium citrate in physiologic solution of sodium chloride is the most desirable. Further bacteriologic studies, using special culture mediums, revealed that a high percentage of the collected blood was contaminated. Several modifications of the method of collection did not eliminate this contamination. Transfusion reactions could not be correlated with bacterial contamination or other detectable factors, such as hemolysis, type of preservative or time of storage. The authors believe that the significance of placental blood is somewhat greater than that of adult blood. Theoretically its use for transfusion is attractive, but the technical difficulties encountered in collection and sterile preservation are sufficient to make its use impracticable under the present state of resources.

Intracystic Papilloma of Breast.—From the microscopic study of fifty-eight tumors of the breast grossly designated as papillomas, Saphir and Parker distinguished three types: the fibrous (pseudoglandular), the glandular and the transitional cell papilloma. Combinations of these types occur, particularly of the fibrous and the glandular types. The fibrous type consists of a stalk of connective tissue. Ramifications of the stalks may fuse with the production of pseudoglandular structures. This is the most common type of papilloma. Because of such pseudoglandular structures, this special subgroup may be designated as the pseudoglandular type. The glandular type is apparently formed by an extension of neighboring hyperplastic or adenomatous periductile acini into a duct or cyst; the epithelial cells of the duct enclose the invaginated acini. Both the fibrous and glandular types are benign tumors which do not recur. They often extend into the neighboring ducts but cannot be regarded as precancerous. The transitional cell type of papilloma morphologically is a benign tumor. It may recur after removal and some of the recurrent tumors may show morphologic evidence of a malignant change. It resembles the papilloma of the urinary bladder which, although morphologically benign, is sometimes classified as carcinoma grade 1 principally because of recurrences which prove to be malignant. Intracystic papillomas of the breast are as a rule multiple. The multiplicity of these transitional cell papillomas may be explained on the basis of multiplicity of origin or by implantations of tumor cells in neighboring ducts. Such implants do not necessarily indicate a malignant condition but may be compared to certain benign ovarian tumors which occasionally produce implantations on the peritoneal surface. Careful microscopic examination of all papillomas of the breast is important as far as the prognosis and the surgical procedure are concerned. For fibropapilloma and glandular papilloma, not only is excision of the tumor indicated but also inclusion of a circumscribed region of the breast surrounding the tumor, because often these tumors are multiple. There is no danger that carcinoma may develop on the basis of these lesions. Simple mastectomy is indicated for transitional cell papilloma, as these lesions, although microscopically benign, may possess an inert degree for malignant changes not recognizable by present staining methods. The prognosis in these cases after mastectomy seems good.

Dilantin Sodium for Convulsive Disorders.—Merritt and Putnam report the results with dilantin sodium of treating 267 patients refractory to other types of therapy. The patients have been treated for from two to twenty-two months. Their ages varied from 2 to 68 years. The duration of seizures varied from less than one year to more than forty years. One hundred and sixty-four of the patients were subject to only one type of attack at the time dilantin therapy was instituted: 124 had grand mal, twenty-one petit mal while nineteen had psychic equivalent or psychomotor attacks. The remaining 103 suffered from a combination of the three types. The results agree in general with those previously reported. Dilantin sodium was most effective in controlling "psychic equivalent" attacks (twelve of nineteen completely relieved), next most effective in preventing "grand mal" attacks (seventy-four of the 124 patients were completely relieved) and least effective in the "petit mal" attacks (six of twenty-one were completely relieved). Of twenty other patients with psychic equivalents associated with grand mal attacks twelve were completely relieved, of 103 with grand mal attacks associated with petit mal or psychic equivalents sixty-three were completely relieved, and such relief occurred in thirty-four of eighty-three patients with petit mal associated with grand mal seizures. The authors have not noticed that the therapeutic effectiveness of the drug becomes less with prolonged administration. They feel, however, that it is too early to draw any conclusions as to the possible development of tolerance to the therapeutic action of the drug as none of their patients have been under treatment for longer than two years. Dilantin sodium was generally well tolerated by most patients. There have been no fatalities and no very serious reactions. The most troublesome symptoms in regulating the dosage were those referable to the gastrointestinal and central nervous systems. Less frequent but more serious symptoms were those referable to the skin (toxic dermatitis) and gums (hyperplasia).

Insulin Treatment of Schizophrenia.—The quality and time of appearance of symptoms following 6,587 insulin treatments exhibited, according to Frostig, a definite and constant order of succession. The progression of symptoms is determined phylogenically and moves in an order inverse to the phylogenetic age of the layers. At first the activity of the cortex becomes suppressed, releasing the syndromes of the basal ganglia. As time progresses activity of the basal ganglia ceases, giving way to a release of the midbrain. Finally centers in the medulla oblongata are released. If the signs of this release last beyond the time at which pinpoint pupils are observed and the corneal reflex disappears, a protracted shock may be expected. Release of the medulla oblongata has to be, therefore, considered the biologic border of the therapeutic application of the insulin effect. The time of appearance and disappearance of symptoms depends on the size of the dose of insulin. Increase of the dose speeds up and decrease of the dose slows the rate of progression. Sensitization is another factor affecting the time of

appearance of the symptoms. The dose does not influence the sequence of the symptoms. In order to adapt the insulin effect on the brain to therapeutic purposes, the author proposed a standard time of five hours. The pharmacologic shock has to be managed so that medullary symptoms (tonic extensor spasms, parasympathetic syndrome) occur in the last half of the fifth hour. The shock seems to be therapeutically sufficient if the tonic phase lasts no less than one hour.

Insulin Therapy of Schizophrenia.—Heilbrunn and Sternlieb state that of 315 schizophrenic patients treated with insulin during the last three years 72 per cent of those with psychoses of less than seven months recovered and 10 per cent had social remissions. The respective figures for patients ill from seven to eighteen months are 35 and 20 per cent, while for patients ill more than eighteen months it is 10 per cent. A similar recovery rate was obtained among patients who had not responded to previous metrazol therapy. There were 15 per cent relapses in the first two groups. Simultaneous treatment with insulin and metrazol did not benefit patients who had failed to respond previously to either form of therapy. No fatalities, serious complications or spinal fractures were encountered. Epileptiform seizures occurring in 33 per cent of the patients had no therapeutic effect. Relapses were especially high among those patients who had had previous spontaneous remissions. The chance of another recovery decreases with each relapse. No definite criteria for a future relapse could be established from the previous patient's history or the symptomatology during the psychosis. Relapses occurred most frequently within six months of completion of treatment. A practical prognostic help was found in the patient's reaction to intravenous sodium amylal. Schizophrenic patients who show little or no response to sodium amylal are apt to fail to improve under insulin, whereas a large percentage of those with a lucid period following sodium amylal respond favorably.

Specific Treatment of Pneumococcal Pneumonias.

Finland and his associates report the results obtained with serums and with drugs separately or in combination in the treatment of cases of pneumonia admitted to the Boston City

Hospital from July 1938 to July 1939. Of 211 patients given specific serum twenty-eight died, of 129 receiving serum and sulfapyridine thirty-one died, of the 225 treated with sulfapyridine forty died and of 472 treated without the serum or sulfapyridine 135 died. In the last group there were seventy-three cases in which the bacteriologic diagnosis was made after death. With these cases excluded the mortality amounted to 15.5 per cent. All the patients were more than 12 years of age. Both horse serum and rabbit serum were effective; the latter was more concentrated and was used in the poorer risks. Rabbit serum gave fewer allergic reactions than horse serum. Severe untoward reactions from either serum or sulfapyridine were infrequent. Sulfanilamide was not effective when given alone or as a supplement to serum therapy. The authors recommend the following treatment for pneumococcal pneumonia: 1. Blood culture and sputum typing should be done as soon as clinical diagnosis of pneumonia is made. 2. Sulfapyridine therapy is to be instituted at this time. 3. Specific serums are to be given to patients having the worst prognosis as soon as the type of pneumococcus is determined. 4. Serum should be given to all patients exhibiting no definite improvement after twenty-four to thirty-six hours of sulfapyridine therapy.

Adenylic Acid in Human Nutrition.—Spies and his co-workers find that in dietary vitamin deficiencies (pellagra, beriberi, riboflavin, vitamin A and vitamin B₂ deficiency) in addition to lack of the specific substance (nicotinic acid, thiamine hydrochloride, riboflavin, oleum percomorphum, carotene in oil or vitamin B₆) the diet is still deficient in another substance or substances when the specific one is supplied. Riboflavin, in addition to its specific effect on clinical riboflavin deficiency, has been shown to be beneficial to certain pellagrins in relapse, and since so many of these "specific" deficiencies are clinically interrelated it is possible that the same general biochemical system or systems may be disturbed. Adenylic acid is a constituent of the pyridine dinucleotides, coenzymes I and II, and is widely distributed in nature. It is intimately concerned with carbohydrate and protein metabolism. The authors investigated the properties of adenylic acid by administering it to eight normal persons and to fifteen persons with mixed vitamin deficiency disease. Some of the symptoms of mixed vitamin deficiency were relieved by adenylic acid. This compound, in some cases, may act in a manner similar to riboflavin in increasing the effectiveness of nicotinic acid in pellagrins in relapse. This not only gives further evidence of the multiple and mixed nature of dietary deficiency diseases in human beings but also suggests that they are the result of dysfunction of certain fundamentally related enzyme reactions. Because of the severe reactions produced by intravenous injections of all preparations of adenylic acid the authors do not recommend that the compound be administered to human beings until further studies have been made. Pellagrins in relapse were benefited by nicotinic acid and adenylic acid. Six patients with malnutrition with intense burning of the oral mucous membranes but with no diagnostic evidence of pellagra were relieved following treatment with adenylic acid alone.

Dystrophic Myotonia.—Waring and his associates state that contrary to general impression dystrophic myotonia is fairly common, is frequently unrecognized and is of great general medical interest. The thirteen cases they report were encountered between 1935 and 1938 by investigating families of patients previously recognized to have the disease. The degenerative changes are so widespread that the ophthalmologist, neurologist or internist may be called on to diagnose and to treat it. From the hereditary features of the disease it appears to be due to a dominant factor first manifested by no signs or by slight signs, notably the cataract. In families in which cataract occurs, its onset at an earlier age in succeeding generations is evidence of a defective gene. Finally there is an evolution of the complete syndrome of dystrophic myotonia in one generation. This is followed at an earlier age in succeeding generations, until in one generation its onset occurs before maturity, after which the disease ceases to appear in that family. It seems probable that the defective gene appears first in a family by mutation. Its onset is insidious and it progresses slowly. Degenerative signs are present for many years before they attract the patient's attention. Therefore the time of its onset is apt to be underestimated by many years. Cataract (twelve of the thirteen patients) is often the earliest evidence of the condition. The prolonged contraction characteristic of myotonia is easily distinguished from simulating conditions by the fact that the difficulty in relaxing the contracted muscle becomes less with each repetition of the contraction, myotonia is not painful, myotonia increases in degree (up to a limit) with increase in the force of contraction and the contractions which show myotonia are voluntarily produced. Contractions have been markedly decreased by the administration of quinine and to a less extent by epinephrine, and by calcium intravenously. The atrophy of myotonia is characterized by involvement of muscles of the face, the sternocleidomastoids, the muscles of the forearm, the quadriceps and the dorsiflexors of the foot. One or more of these muscles usually show the initial involvement, but when the condition is moderately advanced the entire group is more or less affected. Atrophy may affect muscles which have or have not been myotonic. The endocrine system shows evidences of generalized and often marked involvement. Testicular atrophy is frequent. Ovarian involvement is indicated by menstrual irregularities and infertility. The thyroid is often enlarged and of increased firmness. The basal metabolic rate is usually low. The conception of the pituitary as the master regulator of the endocrine system suggests primary pituitary hypofunction as the fundamental cause. Five patients with fairly advanced dystrophia myotonica had hypotension and four low blood pressures. The disease must be differentiated from congenital myotonia, various progressive muscular atrophies and dystrophies and other diseases producing presenile cataracts and endocrine disorders. Its hereditary nature is of the greatest diagnostic importance. Cataract associated with dystrophic myotonia is adequately treated by operation. Myotonia can be adequately treated by quinine. The latter does not, however, influence muscular weakness and atrophy, the source of the greatest disability. The greatest improvement in weakness and atrophy of one patient resulted from anterior pituitary extract, but the extract failed to produce any effect in two. Patients believed aminoacetic acid, epinephrine and epinephrine with pilo-

carpine to be beneficial, but objective signs of improvement were not evident. These drugs may have prevented a progression of the condition. Testosterone propionate was of questionable value.

Metastasis from Breast Carcinoma to Spleen.—Guttman reports an instance of an unusually massive metastasis from a scirrhus carcinoma of the breast to the spleen in a woman of 55 who had noticed a lump in the breast three days prior to hospitalization. Trauma to the breast occurred one year ago and was followed by a swelling. The breast was amputated radically. The postoperative course was rapidly downhill. Eight months after operation there was fluid in the chest, and x-ray examination revealed a metastatic growth in the right lung. Despite extensive irradiation the patient died twenty-two months postoperatively. Metastases to numerous organs were of the gross nodular type. A small and a large nodule were present in the spleen. The metastasis was considered hematogenic in origin, as there was no evidence of involvement of the capsule or of extension along the efferent lymphatics. The mammary tumor was a rapidly growing, medullary carcinoma. Microscopic examination of the small nodule from the spleen showed a neoplasm, consisting of alveolar clusters and broad strands of epithelial cells compactly arranged. These were separated by a stroma consisting of highly vascular, loose connective tissue infiltrated in places with lymphocytes. The cells contained hyperchromatic nuclei which varied markedly in size.

Mitotic figures were numerous. The cytoplasm was basophilic and moderate in amount. Marked degenerative changes were present in the tumor cells in the center of the growth. There was a moderate lymphocytic and plasma cell infiltration at the periphery. The structure of the larger nodule was similar. No structural changes of the pulp of the spleen were to be seen. There were nodular metastases to the lungs, pleura, liver, mediastinum and kidneys.

Constant Dust Feeding Device for Laboratory Use. C. E. Williams and W. P. Battista, New York.—p. 152.

Hazards of Electric and Gas Welding.—Britton and Walsh examined 1,000 welders. Of these 286 had five or more (average nine) years of experience in electric or gas welding. Each roentgenogram of the chest was examined by three physicians. A sick benefit association offered a record of sickness disabilities requiring absence from work for one week or longer of 189 welders. In many instances, serial roentgenograms made over several years were available. No significant change or advance in abnormal markings was observed. The roentgenograms of 186 were normal. Increased hilar shadows or trunk and linear markings were present in forty-seven. These observations are nonspecific and would be found in any critical survey in about the same percentage under similar environmental conditions. Mottling or stippling of the pulmonary fields was present in twenty-four. In at least five of these it could be ascribed to other causes (dust). The remainder gave no history of exposure to dust. Excluding the five, records of sickness of sixteen men show that they have had no serious disability sickness in the last ten years and eight have had no complaints. One has slight albuminuria, two complain of cough and four have lost time within ten years (one in 1933 for four and one-half weeks because of pneumonia, one for two weeks in 1936 because of rheumatism, one for two weeks in 1935 and three weeks in 1936 because of an infected foot and one for forty-six weeks in 1936 because of bronchitis). There has been no recurrence of symptoms. One man lost two weeks because of grip in 1932 and now has a cough and chronic tuberculosis. The group with the most advanced lung changes has no more frequent or severe sickness than any group. Of the remainder

examined roentgenologically, fourteen men have signs of glaucoma, four large or multiple calcified foci, three rather extensive tuberculous changes, four widespread calcific deposits of a mycotic or disseminated healed tuberculous infection, two signs of emphysema and one each had a widened aorta, enlarged heart shadow, fractured rib and calcified pleura. These changes probably have no causal relationship to occupation. Only thirty-four of the 286 showed any abnormality or offered any physical complaint, not one of which was of a disabling degree. Twenty-two of the complaints were related to the respiratory system. The disabilities of the 189 welders were of the nature expected in any group of workers. One hundred and thirty-three had had no disability due to sickness lasting one week or more. In 1937 fourteen welders had sickness causing an absence from work for an average of 5.7 weeks each, while for the general employee group the average disability was 5.5 weeks each. The health of the welders compares favorably and perhaps is better than that of other groups in the same manufacturing unit. The hazards common to all types of welding include heat, light rays, electric shock and burns, irritating or poisonous gases, fumes or dust. When proper safeguards are taken for their control they should offer no serious menace to health.

Sympathetic Neuroblastoma: Report of Case. O. B. Fesenmaier, New Ulm.—p. 244.

Apical Lung Tumors.—Moersch and his associates state that among the admissions to the Mayo Clinic from January 1928 to Dec. 31, 1937, there were only thirteen cases of superior pulmonary sulcus tumor with all of the essential features of the disease present. Four other cases had all the features but the Horner's syndrome. These four cases tend to disprove the contention that the tumor is a distinct clinical entity. Thirteen of the patients were men and four were women. The youngest was 19 years of age and the oldest 72; the majority were middle aged. The left apex was involved in twelve cases. Intermittent pain, worse at night, was the earliest and most annoying symptom. It usually began near the shoulder and tended to spread down the arm and round the scapula on the homolateral side. Before Horner's syndrome develops the condition is often mistaken for "rheumatism," neuritis or even angina and, when the pain is suspected of being of "rheumatic" origin, tonsillectomy for relief is not an uncommon event. The condition is rapidly progressive and disabling. Careful x-ray examination of the thorax is of utmost diagnostic importance. Hemoptysis is infrequent. Tissue for microscopic examination was obtained from nine of the thirteen cases and from three of the four cases in which Horner's syndrome was absent. Necropsy was performed on two from each group and all observations were regarded as those of primary carcinoma of the bronchus with metastases to other organs. Three of the thirteen typical cases were explored surgically and in each instance the tumor was inoperable because of invasion of the vertebrae or ribs. Tumor tissue from two of the three cases was reported as adenocarcinoma, grade 1. Biopsy of the supraclavicular lymph nodes overlying the apical

tumor from four of the typical cases and from one of the atypical cases revealed that four were cases of adenocarcinoma and one a chondroma. The prognosis of an apical pulmonary tumor is grave. The majority of such patients under the authors' observation were dead within six months of the initial examination. No successful form of treatment has been found. Occasionally, temporary relief was obtained from roentgen therapy. The authors conclude that the so-called superior pulmonary sulcus tumor is not a distinct clinical entity but a lesion situated in the apex of the lung, giving rise to a characteristic train of symptoms designated by Pancoast as the superior pulmonary sulcus syndrome. The tumor that most commonly produces this symptom complex is a primary carcinoma of the bronchus.

Sulfanilamide in Scarlet Fever.—Bozalis and Barnett treated 300 cases of scarlet fever with sulfanilamide administered orally in a dose of 0.2 Gm. per kilogram of body weight ($1\frac{1}{2}$ grains per pound) for the first twenty-four hours, in six divided doses, decreased one half after twenty-four hours for the remainder of the period of drug treatment. Children weighing over 88 pounds (40 Kg.) and adults received 8 Gm. in the first twenty-four hours in six doses, after which they received 4 Gm. daily in six doses. Blood concentrations between 5 and 10 mg. per hundred cubic centimeters were thus obtained within a few hours and maintained throughout the course of treatment. The drug was continued after the temperature had been normal for two days and when there was a definite improvement in the appearance of the throat. There was an apparent reduction in the number of septic complications which might have been further reduced had the drug been continued longer. When complications did occur, a prompt response to further sulfanilamide treatment took place. The authors performed tonsillectomies on forty of convalescing patients with no reactions despite the fact that these were carried out during the winter and spring months and in the presence of active infections. This was ascribed to administration of sulfanilamide before and after the operation. Scarlet fever antitoxin in combination with sulfanilamide was given to thirty-nine patients with extreme degrees of toxicity. There were no deaths.

Atypical Bronchopneumonia.—Murray during the last four years observed a mild form of pneumonia among the students at Harvard University. It was especially prevalent during the academic year 1938-1939, eighty-one cases having been cared for in the Stillman Infirmary and thirty-nine cases reported by family physicians. The records of 132 infirmary patients were studied. The disease began as a simple acute infection with minimal respiratory symptoms but usually with the early appearance of cough and later some degree of expectoration. The chill, chest pain, bloody sputum and prostration

of pneumococcal lobar pneumonia were as a rule absent. A pulmonary lesion, most often beginning at the hilus and advancing outward toward the lateral chest wall or the diaphragm, was demonstrable early in the illness by x-ray examination. Physical signs were minimal. Mild dullness to percussion and some diminution in breath sounds, followed by the appearance of coarse rales on the fifth, sixth or seventh day, were the usual observations. The course was mild, with return of the temperature to normal in from five to seven days. The pulse was only moderately accelerated, rarely rising above 90 or 100. The respiratory rate was almost invariably normal. Severe prostration was present in a few cases, but tympanites, delirium and other evidences of critical illness were not seen. The leukocyte count was either normal or slightly elevated, with from 70 to 75 per cent polymorphonuclear cells. In about one third of the cases there was a rise in the leukocytes during the latter part of the illness, without the appearance of complications to explain it. Complications were few and mild. The majority of sputum specimens examined contained no pneumococci; somewhat less than half showed a pneumococcus, usually one of the higher types. Sputum cultures yielded a variety of organisms, and a small number of blood cultures were all negative. Attempts to isolate a filtrable virus were unsuccessful. A short convalescence was the rule. No deaths occurred. The author believes that this infection represents a separate disease entity but does not believe that it is a new disease. It does not appear to be related to the common cold or to epidemic influenza. Epidemiologic observations indicate that it is contagious and suggest an incubation period of from seven to eleven days. Bacteriologic studies fail to incriminate any of the known bacteria as etiologic factors. This negative evidence, plus certain characteristics of the clinical picture, suggests that this is a virus disease. So far, however, no positive evidence in favor of this impression has been obtained.

Acute Mechanical Obstruction of Small Bowel.—This is the fourth report on patients with acute mechanical obstruction of the small bowel operated on at the Massachusetts General Hospital and is based on 136 cases treated during the last fifteen years. McKittrick and Sarris emphasize the following principles in the management of these cases: The degree of dehydration and chemical imbalance must be evaluated and methods instituted for relief. Blood transfusions may be indicated for patients with strangulation obstruction. A double lumen Miller-Abbot or similar tube should be passed immediately, to be left in whether or not operation is undertaken. Immediate operation is indicated in any case examined within twenty-four hours after the onset of symptoms. Early operation should be done on a patient seen in the second twenty-four hours. Delayed or nonoperative treatment is indicated in the absence of definite signs of strangulation obstruction in any patient seen later than forty-eight hours after the onset of symptoms, or in any patient over 60 years of age, unless the obstruction is of less than twenty-four hours' duration and the patient is in good condition, without distention. If conservative treatment is instituted, the following routine should be followed: serial abdominal films at from twelve to twenty-four hour intervals, in order to follow the progress of the tube and the degree of distention; bi-daily white cell counts, and frequent abdominal examination, at least every four or six hours, with the examiner particularly alert for the development of local tenderness or of rebound tenderness. If decompression cannot be accomplished by intubation, and laparotomy under general or spinal anesthesia seems too hazardous, the distended bowel should be drained by inserting a catheter in a distended loop under procaine anesthesia. No attempt at exploration should be made at this time. If decompression is successfully accomplished and normal bowel action is reestablished, an operation of election at the same hospital admission for a good risk patient should be

given serious consideration. The authors feel that since the obstructing mechanism is probably still present, and since 26 per cent of their patients have given a history of previous attacks, the risk of lysis of the point of obstruction is less than that of future obstruction, unless the patient is assured of competent surgical care within the first twenty-four hours of any subsequent attack.

Engorgement of Pulmonary Veins.—Reid presents reasons in support of the conception that compression of the pulmonary veins and of the lungs by extension of cardiac enlargement posteriorly is a more valid explanation of engorgement of these vessels and of dyspnea of cardiac origin than is the formerly accepted theory. There exist similarities to what is known as the postmediastinal syndrome in which dyspnea is a prominent symptom. Patients with heart disease were closely questioned regarding the occurrence of dyspnea while they were in bed. Their answers were correlated with the fluoroscopic evidence of the backward extension of their hearts. Patients with proved disease of the heart and usually with some degree of cardiac insufficiency, but whose dyspnea was unrelated to posture, served as controls. There were fifty-three patients in all—seventeen with postural dyspnea and thirty-six without. The former were all found to have marked extension of the heart backward into the retrocardiac space, whereas but one of the control cases showed marked encroachment on the retrocardiac space. The author does not assert that these prove that engorgement of the pulmonary veins is caused by mechanical pressure exerted on their walls by backward extension of an enlarged heart. It seems reasonable to suggest that physicians should not limit their thoughts to the heart in cardiac patients with dyspnea. Some therapeutic possibilities come to mind. It might be advisable to pay more attention to the posture of the patient. There are patients in whom elevation on a bed rest gives but partial relief to dyspnea but who will obtain greater ease in a forward leaning posture. The author adjusted a hospital bed table in front of such patients and found that it lessened their dyspnea. Crowding of the available space in the thorax by accumulations of fluid is an evident reason for increased dyspnea. An increased application of and a readiness to repeat thoracentesis have increased the comfort of patients. It seems reasonable to suggest the performance of the Brauer operation.

Spontaneous Pneumothorax.—According to Norris, spontaneous pneumothorax occurring in active, symptom-free persons is benign and but rarely associated with tuberculosis. He reports twenty-five cases seen at Kodak Park during the last six years. He believes that the condition should be designated as benign spontaneous pneumothorax. It occurs, as a rule, in persons between the ages of 19 and 35 years. Two thirds of his patients were underweight. All except one were males. Spontaneous pneumothorax should be suspected in the presence of acute pain in the chest, upper part of the abdomen, or back. The acute onset at times may suggest acute cholelithiasis, renal calculus, angina pectoris or perforation of a peptic ulcer. Spontaneous pneumothorax is seldom associated with any usual physical exertion and is never symptom free. Diagnosis may

be made from physical signs, but the condition can be ruled out only by roentgenograms taken in forced expiration. This is the only way in which small collections of air can be demonstrated. Fluoroscopy is of little use except in marked cases. Usually the spontaneous pneumothorax requires no treatment beyond bed rest. Occasionally in the "ball valve" or tension type it is necessary to remove some air by paracentesis. Tuberculosis should be suspected but is only rarely associated with this condition. Even in the presence of roentgenograms indicating healed tuberculosis foci, long periods of hospitalization are an unnecessary hardship. Tuberculin reactions are useful. Tuberculin tests made on fifteen of the twenty-five patients were negative in seven, mildly positive in six and positive in two cases. Loss of time ranged from none to five months, the longest disability being in a patient with a suggestive apical scar. The average lost time was 3.84 weeks.

Equine Encephalomyelitis in the United States.—The incidence, mortality and distribution of equine encephalomyelitis in the United States reported for 1939 (8,008 cases) was only about 4 per cent of the number of cases (184,662) reported in 1938. There were 2,471 deaths from the disease. These figures give a case rate of 1.1 per thousand animals (horses and mules) in the affected counties and a case fatality of 30 per cent. The case fatality rate for the eastern type of virus was apparently more than three times as high as that for the western type. In twenty-four states in which only the western type was proved or suspected the case fatality was 26.7 per cent, as compared with 89 per cent in nine states in which only the eastern type was proved or suspected. More than 90 per cent of the cases were reported to have occurred during the summer or early fall. This seasonal prevalence tends to support the pre-

vailing conception regarding the principal natural means of transmission, by blood sucking insects, especially mosquitoes. The reported incidence of encephalomyelitis in vaccinated and unvaccinated horses and mules was 0.37 and 1.2 respectively per thousand animals. No less than 3,000,000 horses and mules (about one fifth of the total in the United States) received specific prophylactic treatment. Vaccination and the retarding of insect breeding appear as the major factors in the control of the disease in animals and its transmission to man.

- *Bacterial Endocarditis and Syphilitic Heart Disease. C. H. Boyd, Baltimore.—p. 47.
- Medical Management of Gastric and Duodenal Ulcer. S. Morein, Providence.—p. 52.

Bacterial Endocarditis and Syphilitic Heart Disease.—Boyd believes that bacterial endocarditis superimposed on syphilitic valvulitis occurs more frequently than the literature would indicate. Eleven cases are reported in the literature in which it is possible to conclude that a preexisting syphilitic lesion of the aortic valves formed the base on which a secondary infection might have become implanted, and two in which a syphilitic aortitis was present on which vegetations had developed but which showed no valvulitis. These reports appeared within the last twenty years, and about one half in the last five, suggesting an increasing interest in the subject and the possibility that the two processes occur more frequently than has been thought. The necropsy protocols of 8,100 cases at the Baltimore City Hospitals contained 105 instances of bacterial endocarditis. Fourteen were felt definitely to be satisfactory examples of vegetative bacterial endocarditis superimposed on old syphilitic aortic valve disease. Because of lack of material for microscopic study, eight cases were discarded. In the six there was a history of syphilis, positive serologic tests or a history of antisyphilitic treatment. There was gross and microscopic evidence of syphilis of the aortic valve cusps and aorta with absence of valvular changes suggesting other pathologic processes, the vegetations were located and bacteria were demonstrated. Cases of terminal bacterial endocarditis were excluded. Of the six proved cases, all were in Negroes from 30 to 44 years of age. The onset of symptoms was considered acute in only one instance. The duration of symptoms attributable to the bacterial infection before admission varied between seven days and eight months, the period of hospitalization before death between two days and two months and the entire course of illness being nineteen days and two, three, two, seven and eight months respectively. Temperature elevations of only two were significant. Chills were not a feature in any case. Five of the six patients showed rather marked cardiac enlargement, four presented an aortic diastolic murmur, while in one a murmur developed in the course of the illness. Splenic enlargement was noticed in only one case. Petchiae were not seen clinically in any instance, nor were there any embolic phenomena which could be attributed to the breaking off of vegetations. In none of the six cases was it suspected clinically that bacterial endocarditis had existed. This may have been responsible in some instances for failure to observe some of the more classic clinical signs of the disease: petchiae, splenic tumor and hematuria. Five of the patients were admitted with cardiac failure and the sixth with lobar pneumonia. These features apparently overshadowed the bacterial endocarditis. Clinical diagnosis of the association of bacterial endocarditis with syphilitic valvular disease is at best difficult, but it should be suspected in any case of supposed syphilitic aortic insufficiency with a continuous febrile and progressively downhill course, especially if any of the classic signs are present.

Thyroid Disease in the Southern Negro.—According to Boyce, 952 patients with thyroid disease were treated at Charity Hospital in the course of the twelve and one half years ended July 1938. The white incidence (470 cases) was 1:691 in 324,969 admissions and the Negro (482 cases) 1:503 in 242,245 admissions. A consideration of the figures from the standpoint of toxicity disposes of the idea that toxic thyroid disease is rare in the Negro. It follows rather roughly the ratio of Negro and white hospital admissions. The diffuse variety of toxic disease is more frequent than the nodular in the Negro, although in nontoxic disease the reverse is true. Far more striking than the variations in the incidence are the disparities in mortality. The mortality for the whole series of 952 cases was 5.3 per cent; the Negroes furnished almost two thirds of the mortality. The total male mortality of 14.3 per cent, or fifteen of 105 cases, was more than four times the female mortality of 3.5 per cent, or thirty-three of 847 cases. In Negro women the mortality was higher than in white women in both varieties of nontoxic disease. In both varieties of toxic disease it was more than twice as high. In Negro men the death rate far exceeded the death rate of white men in all varieties of the disease and in the toxic variety it rose to shocking figures. These disparities are beyond explanation, as no argument would seem to apply to the Negro male which does not apply to the Negro female as well. In both Negro and white subjects the mortality for diffuse toxic disease is higher than for nodular toxic disease. This circumstance is also difficult to explain, as in nodular toxic disease the hazards of cardiac disease and other visceral damage are added to the inherent hazards of toxic thyroid disease. More than two thirds of all the patients were treated during the last five and one half years of the study and almost three fourths of the Negroes were treated within this period. In recent years the white mortality has shown some improvement, but the Negro mortality has continued very high, which perhaps is further evidence of the inherently more serious character of this disease in the Negro race. The author cites several studies by other workers which support indirectly his contention that toxic thyroid disease in southern Negroes, as is usual in endemic areas, seems to arise on the basis of a previous nontoxic diffuse goiter, whereas in white subjects it arises as a virgin pathologic change. The simple type of goiter, which amounts to little more than an enlargement of the neck, is fairly frequent in young Negro women. Of a number of such patients observed for several years the gland has either not increased in size or has decreased. Therefore it seems that symptomless thyroid enlargements in young Negro women in

this community should be operated on only after a period of observation. This type of goiter gives rise to no symptoms and in most cases no further pathologic change occurs. In the natural cycle the diffuse toxic stage wears itself out and the gland passes over into the nontoxic stage. Whether or not toxic manifestations reappear depends on whether or not the stimuli, known or unknown, which were responsible for the original activity again become effective. This cycle of events accounts for the fact that nontoxic nodular goiter formed 34 per cent of all the Negro cases against 25.5 per cent of the white cases. It is possible that in some instances the gland may return to the original colloid or resting state. This surmise is supported by the fact that there were forty-five cases of diffuse nontoxic goiter in Negroes more than 40 years of age against twenty-two cases in white persons. Part of the Negro mortality is undoubtedly to be attributed to the inadequate and overcrowded hospital facilities and part of it can be explained by the racial tendency to delay medical consultation. Adequate exposure of the glands is often difficult in Negroes owing to the fact that because of physical labor their neck muscles are highly developed. A study of the causes of death in the two groups of patients furnish proof of the serious character of both nontoxic and toxic thyroid disease in the Negro. The hippuric acid test of hepatic function performed on 130 patients, eighty-five of whom were Negroes, shows that in all varieties of thyroid disease hepatic function is lower in the Negro than in the white patient. Whatever the reason for a decreased hepatic function it probably explains part of the high Negro mortality. However, proper preparation will in most cases overcome the visceral damage. No data to explain the etiology of goiter in the Negro are to be had.

Spontaneous, Threatened or Habitual Abortion.—Collins and his associates used wheat germ oil in the treatment of thirty-six cases of spontaneous, threatened or habitual abortion in combination with progesterone and/or thyroid. The daily maintenance dose ranged from 1 to 1½ drachms (4 to 6 Gm.) unless the patient showed signs of threatened abortion, when from 8 to 12 drachms (32 to 48 Gm.) was given during the first twenty-four hours and then they were placed on the daily maintenance dose. Oil was given until patients reached from eight to eight and one half calendar months of pregnancy. Anterior pituitary-like gonadotropic substance in the form of antuitrin S was administered intramuscularly in 1 cc. doses given at weekly intervals until the patient was pregnant from four to four and one half calendar months. In a few cases injections were continued until the seventh calendar month. One rabbit unit of progesterone was administered daily intramuscularly when cramping or bleeding was actually present and, when the symptoms ceased, antuitrin S was substituted. Thyroid extract in from one tenth to one half grain (0.0065 to 0.03 Gm.) doses twice daily was given to all patients showing evidence of hypothyroidism: obesity, irregular menstrual periods, slow pulse and the like. Cases were classified as "threatened abortion" if cramping pain in the lower part of the abdomen persisted longer than twenty-four hours or if a patient had bleeding and as "habitual abortion" if the patient had had two or more spontaneous abortions or had had one previous abortion immediately prior to or attempted to abort during her present pregnancy. Of twenty-four patients with threatened abortion treated three went to completion despite therapy. Of the remainder, fourteen have been delivered of normal, full term children, one has now passed the period of viability, and the remainder have retained their pregnancies without further signs or symptoms of abortion. This represents a successful arresting of the abortion in 87 per cent of these cases. Of twelve habitual aborters eight have been delivered of normal, full term, healthy infants, while another is now pregnant six and one half calendar months. Three patients aborted despite treatment. In one of these the abortion was precipitated by an attack of malaria. These twelve women, prior to treatment, had a total of twenty-one pregnancies resulting in only three live births.

Etiology and Treatment of Ulcers of Leg.—Zimmerman and Faller assert that the majority of leg ulcers are associated with diseases of the veins. Whether due to varicose veins or to deep thrombophlebitis, they are essentially infectious in origin and develop on the basis of periphlebitic infiltraton

and cicatrization. They are similar in pathogenesis and clinical manifestations and respond to similar forms of therapy. The essential predisposing pathologic change is ischemia from inflammatory sclerosis of the skin and subcutaneous tissues. External secondary infection adds to the fibrosis and circulatory insufficiency. The tissue changes are permanent and irreversible and the ulcers may persist or continue to evolve even after the associated varicosities are completely eradicated. From the various therapies for crural ulcers, one fact survives; gentle, mechanical pressure. Mechanical measures have been the mainstay of the authors' therapy for ulcers and eczemas of venous origin and are relied on almost to the exclusion of all other forms of treatment. They have come to believe that ulcers of the leg do not, as a rule, constitute a difficult problem. Treatment is almost invariably ambulant; bed rest and elevation are rarely found necessary. The patients are permitted to go about their usual affairs without restriction as long as the pressure bandages are in place. Frequently healing of ulcers by ambulant treatment has been accomplished when prolonged bed rest had failed. Recumbent management is limited to the small group of patients who do not tolerate occlusive dressings and to those with acute infection severe enough to demand bed rest. For obtaining gentle elastic pressure, Unna's paste boot is relied on not only for the treatment of ulcers but also for other complications of varicose veins, including local phlebitis, phlebitic indurations and varicose eczemas. Occasionally if in long standing callous ulcers, after the usual initial rapid improvement, the tempo slows down, renewed stimulus may be obtained by strapping the ulcer with strips of adhesive tape and by applying the boot over the strapping. If this stimulus also wears off before the ulcer is healed, further acceleration may be secured by applying pads of rubber sponge under the boot. At first the boots are changed once a week. Later when edema has subsided and the amount of exudate has diminished they may be left on for two or three weeks or longer. Patients are instructed to return with boots on. They are removed in the clinic, the limbs are cleansed and the new boot is applied. When healing is complete, further protection with Unna's paste or elastic bandages for several weeks longer is advised until the scar is sufficiently firm and tough. Post-thrombophlebitic limbs with persisting edema may require permanent supportive bandaging to prevent swelling and a tendency to further ulceration. Concomitant varicosities should be eradicated and associated local and general conditions attended to.

Prevention of Adhesions.—For the preparation of amnioplastin, amniotic membranes received from the delivery room are washed in water to remove as much of the blood and mucus as possible. The inner membrane (the amnion) is freed from the outer membrane (the chorion) by finger dissection. The membrane is again washed in water and placed in 70 per cent alcohol. The thin membrane is stretched, dried in sheets of convenient size and preserved dry or in 70 per cent alcohol until such time as final sterilization can be carried out. Sterilization is accomplished by autoclaving or boiling the sheets in distilled water. A thin, pliable, transparent membrane is produced in which there is no cellular structure. Amnioplastin is placed in Ringer's or physiologic solution of sodium chloride for twenty minutes and then flattened out between glass plates. Chao and his associates examined cats at intervals varying from ten to sixty days after the surface of the lacerated brain had been covered with this membrane. At necropsy it was found that a new dura had formed. In no instance was there evidence of gross adhesion. The amnioplastin sheet disappeared progressively. At thirty days no gross or microscopic evidence of membrane could be found. Remains of the amnioplastin could be seen as an amorphous substance without cellular structure. There was evidence of beginning regeneration of the dura and pia. By twenty days the dural defect had completely filled in, the pia had partially closed over the destroyed brain, and the membrane between the two was represented by a thin amorphous material. The authors recommend amnioplastin for clinical use when a craniotomy is carried out and the brain is exposed for a considerable time or when the brain is injured as by the removal of a tumor. The amnioplastin is to be interposed between dura and brain, both when the brain is intact and when it is lacerated. The authors used it for this purpose and believe that local postoperative edema is thus lessened. There was no increase in immediate cellular reaction in the spinal fluid. It has not been used long enough to determine its effect on the incidence of postoperative epilepsy. Wounds of the brain should be treated according to the best established principles, and amnioplastin should be spread over the wounded surface to prevent meningocerebral adhesion. If there is a defect in the dura as well as in the pia, amnioplastin will provide for the reformation of dura and pia as separate layers. The membrane permits regrowth of leptomeninges over the brain even after cerebral laceration. It provides for the restoration of the subdural space. It should serve in other military and civil surgical fields to prevent adhesions in the peritoneal and joint cavities and about tendons and sutured nerves.

Hemorrhage from Rupture of Intracerebral Aneurysm.—Hermann and Macgregor cite an instance of a congenital intracerebral aneurysm in a boy $4\frac{1}{2}$ years old. He had been in excellent health until symptoms of cerebral hemorrhage occurred. Shortly after admission to the hospital, breathing ceased; the pulse remained of good quality. A tracheal tube was inserted and artificial respiration was maintained. Exploratory cranial perforations were made in each parietal region but no collection of blood was found. A cannula on each side was directed through the brain toward the lateral ventricle. When the ventricular cavity was entered, fluid blood with fragments of clot and disorganized cerebral tissue escaped from each cannula. From this it was surmised that a massive intracerebral hemorrhage had occurred and had ruptured into one of the ventricular cavities probably producing severe damage to the brain substance. No further active treatment was attempted.

The child died fifteen hours after the onset of symptoms. Post-mortem examination revealed that the hemorrhage from the aneurysm had occurred much earlier than that of the fatal rupture. It was supposed that there was only a limited leakage of blood at this time, as no clinical history suggestive of an earlier "cerebral catastrophe" could be elicited. It was probable that at least a part of the fibrous thickening which affected the major portion of the sac wall was the result of this earlier blood clot. These events were probably of long standing, as the fibrous tissue of the sac wall was mature and relatively acellular. Two congenital defects of the muscular coats were found in relation to the junction of branches of the anterior perforating group of arteries with the left middle cerebral artery. The defects were at the acute angle of the junction in each case. There was a gap in the muscular coat, which was filled by fibrous tissue continuous with that of the adventitia. The internal elastic lamina was intact and the tunica intima was unaltered. Except for these microscopic defects at the branch junction lines the structure of the cerebral arteries was normal.

Estrogenic Properties of Stilbestrol Dipropionate and Hexestrol.—Bishop and his associates treated sixty-six cases in which there were menopausal symptoms and found that eight did not react to stilbestrol dipropionate, to hexestrol or to both. Of thirty-six cases of atrophic vaginitis, one case did not respond either to the dipropionate or to hexestrol. Thus, in 102 cases presenting subjective and/or objective menopausal manifestations relief was obtained in ninety-three (91.2 per cent). Of the sixty cases treated with stilbestrol dipropionate six (10 per cent) did not respond. Of the sixty-three cases treated with hexestrol seventeen (27 per cent) did not respond. The higher percentage of failure with hexestrol was probably due

to the relatively lower dosage. In forty-eight cases of amenorrhea, menstruation was induced in twenty-eight by stilbestrol dipropionate or by hexestrol or by both. Of thirty-one cases treated with stilbestrol dipropionate nine did not respond; nor did twenty out of the twenty-seven cases treated with hexestrol. These rather poor results are undoubtedly due to low dosage. The two substances gave poor results in a small group of cases of dysmenorrhea and uniformly successful results in inhibiting lactation. Toxic by-effects were noted in twenty-three of 155 cases of the present series. They were usually transient and mild, such as nausea and occasionally vomiting and constipation. The authors conclude that stilbestrol dipropionate and hexestrol have estrogenic properties similar to those of stilbestrol. Toxic effects, though not severe, developed in 21.6 per cent of the cases treated with stilbestrol dipropionate and in 4.5 per cent of the cases treated with hexestrol.

Blood Urea and Urea Clearance.—Morton and Nussey investigated the effect of large doses of urea on the clearing capacity of the kidneys. Their results confirmed previous observations that the Van Slyke technic often yields in normal subjects clearance values well below the accepted standards. Nineteen of fifty normal subjects failed to qualify as normal. Normal values for urea clearance were obtained after the administration of a 15 Gm. dose of urea by mouth. In parallel experiments on patients with evidence of renal disease the ingestion of urea did not improve the clearance figures, and a fall was often recorded in such cases. The authors saw no harm resulting from giving this heavy dose of urea to patients with an already high level of blood urea, though they think that this procedure would not commend itself as a routine in cases of uremia or in the acute phase of nephritis. Frequent collections of specimens of urine and of blood after the ingestion of urea made it possible to follow its effect on the functional capacity of the kidneys. Calculation of the urea clearance over any period of time must be based on the knowledge that the blood urea remains reasonably constant throughout. The degree of constancy of this factor after the administration of urea by mouth depends largely on the rate of absorption of urea from the bowel and of its disposal from the blood stream by the kidney. A study of blood urea curves, based on half-hourly observations, demonstrates that a relatively stable period exists between three-quarters and one and three-quarters hours after the administration of urea by mouth. The blood urea observed at one and one-quarter hours approximates closely the mean calculated from the three-quarters hour and one and three-quarters hour values. The authors criticize the procedure which Fowweather proposed for the Van Slyke clearance formulas to specimens obtained after the administration of urea by mouth and recommend the following modification: The patient is allowed to have his usual meal the night before. On the morning of the test a breakfast of bread, butter and a piece of fruit, with one small cup of tea, is permitted. Two hours later the patient empties the bladder and immediately afterward 15 Gm. of urea in 200 cc. of water is given. The bladder is again emptied after forty-five minutes and the exact time recorded. This is repeated an hour later. Midway between the two a specimen of blood is obtained. The urea clearance is calculated from the data obtained from analysis of the third specimen of urine.

*Traumatic Diabetes Insipidus. J. Bréhant.—p. 205.

Traumatic Diabetes Insipidus.—Bréhant reports a case of traumatic diabetes insipidus which he observed daily for four months after the occurrence of the trauma. A woman aged 41 was hurt in an automobile accident. Examination revealed fracture of the nasal bones and a painful spot at the level of the left temporomaxillary articulation. The next day left oculopalpebral ecchymosis, polydipsia, polyuria, loss of smell and decrease in vision were observed. X-ray examination disclosed a radiating frontal fracture at the roof of the orbit, fracture of the left temporal bone, and opacity of the left frontal sinus and right sphenoid sinus suggesting a hematoma. Diabetes insipidus in this case was caused either by a hemorrhage occurring within the tuber or by pressure of a hematoma at the level of the floor of the third ventricle. The patient was treated with estrogenic substance, lumbar puncture, a salt-free diet, subcutaneous injections of solution of posterior pituitary and posterior pituitary administered in a powdered form into the nose. The latter two and particularly the last method were effective. Diuresis decreased considerably while treatment was being administered. Diabetes insipidus as a complication is observed as a rule after frontal and temporal trauma. It may be caused by direct traumatic lesion of the diabetogenic centers, by foreign body, by compression caused by a hematoma, by intracranial hypertension, by involvement in a fracture callus, by hypertrophic pachymeningitis, by fracture osteitis of the sphenoid or by posttraumatic gliomatous neoplasms. Polyuria and polydipsia are the main symptoms. There may appear other morbid manifestations pointing to complex changes in the infundibulum and the hypophysis. In addition to the center of water metabolism, that of fat, as well as sexual and hypnic functions, may likewise be involved. The seat of these lesions has not been definitely located. Some believe it to be in the hypophysis, others in the infundibulotuber. The prognosis in traumatic diabetes insipidus is encouraging but requires constant care. The treatment consists chiefly of hypophysial therapy administered hypodermically or still better of a powdered hypophysial substance administered intranasally. The latter form of treatment produced the best results. Early surgical attention at the time of traumatism may favorably influence the course of the disease in some instances.

Stilbestrol in Endocrine Therapy.—Wenner administered stilbene preparations orally to nine women who had undergone roentgen castration for menopausal hemorrhages some two years previously. Two 5 mg. tablets were given every three or four days until a total of 60 mg. had been reached. This dose produced a glandular hyperplasia, while from 25 to 30 mg. was sufficient to produce thickening of the quiescent endometrium. The subsequent administration of progesterone resulted in true menstruation and an enlargement of the uterus. Hot flushes, vertigo, headaches and pruritus vulvae were noticeably improved. Stilbestrol was administered to fourteen women to prevent lactation and to thirty-seven to inhibit it. Two 5 mg. tablets given during the first twenty-four hours after delivery prevented lactation in all but three. The author suggests that in at least one of these cases the drug might have been given

too late. He suggests that 2 or 3 mg. of stilbestrol be given by injection during the first hours after delivery and the effect of this injection be supported by oral medication for the next two days. The required dosage fluctuates individually. The arrest of an existing lactation is more difficult than is its prevention before onset. Two 5 mg. tablets given on five successive days usually arrest the lactation. Secondary effects necessitating interruption of medication were comparatively rare in a series of eighty cases. Nausea developed in two and vomiting and vertigo in one.

Sulfapyridine in Epidemic Meningitis.—Treatment of epidemic meningitis at the children's hospital in Zurich consists, according to Jäckli, in oral administration of sulfapyridine in a daily dose of 1 Gm. for each 10 Kg. of body weight. This quantity is distributed evenly over the twenty-four hours at four hour intervals. The medication is continued until the cerebrospinal fluid is clear (from 50 to 150 cells per cubic millimeter) and meningococci are no longer demonstrable, which is usually the case in from two to five days. The dose is gradually decreased and the medication is terminated between the eighth and the twelfth day. The individual doses at the onset are somewhat larger in order to reach the desired concentration in the blood and cerebrospinal fluid as soon as possible. Lumbar punctures are made twice daily in the beginning, control punctures occasionally. The treatment is often begun with a blood transfusion. Serum is not given. Cardiac and circulatory stimulants are employed according to need. Intramuscular injections of sulfapyridine are employed when oral medication is not tolerated. Sulfapyridine by intravenous drip is another valuable mode of administration. It makes possible the administration at the same time of nutrient substances and fluids. It is reserved for comatose patients and for patients with primary uncontrollable vomiting. The daily dose of soluble sulfapyridine is added to the infusion fluid of a 5.5 per cent solution of dextrose in Ringer's solution. Cardiac and circulatory stimulants may be added to the infusion fluid. The drip infusion is continued only as long as absolutely necessary, usually from two to five days. The author employed this therapy for sixteen children with epidemic meningitis admitted during the epidemic of December 1939 to February 1940. The ages of the children varied between 6 months and 15 years. They were either completely cured or had advanced far in their convalescence at the time of the report.

Procaine Hydrochloride in Acute Inflammations.—Montanari Reggiani reports the effect of local infiltration with procaine hydrochloride in acute circumscribed inflammatory processes in twenty-six cases. From 2 to 4 cc. of a 1 per cent solution of procaine hydrochloride was injected in cases of circumscribed inflammation and from 20 to 40 cc. in more extensive acute inflammation. The infiltrations were carried out as for regional anesthesia, the solution being injected slowly into the inflamed tissues daily for the first two or three infiltrations and every other day for the last two. The total number of infiltrations varied from two to five. The first injection relieved the pain within the first hour and brought on an immediate reaction of transient aggravation of the symptoms, except that of pain. The reaction lasted from twelve to twenty-four hours and was followed by rapid regression of inflammation and infiltration and by limitation of the local process. Subsequent infiltrations were effective in controlling pain and in accelerating the regression of inflammation and suppuration. Clinical recovery was obtained in from three to six days. The clinical improvement was paralleled by alterations in the leukocyte count of the peripheral and the focal blood and the conversion of the acid reaction of the pus to an alkaline one. The neutrophilic leukocytosis, diminu-

tion in the monocytes and lymphocytes and the absence of the eosinophils, and the leukopenia of the focal blood were changed to a normal blood picture after the treatment. The author concludes that infiltrations of procaine hydrochloride bring about a stimulation of local and general immunity by which inflammation and suppuration are controlled.

Hemorrhagic Purpura with Granulocytopenic Reactions.—Oettel and Thaddea describe an unusual case of acute essential thrombopenia with granulocytopenia in which blood transfusions and a combined vitamin C and liver extract therapy effected a prompt recovery. The patient was a man aged 38 whose familial and personal history was good. A septic angina with high fever induced a painful gingivitis. After several weeks small red spots appeared over the entire body, increasing in intensity. Military exertions aggravated the condition. Pains set in extending from the abdomen to the small of the back. Blood appeared in the urine and in the expectorations. At this stage he was hospitalized. The general tendency to cutaneous bleeding was found to be especially localized in the joint flexures. Three small painful necrotic areas were observed on one side of the mouth near the upper molars. Laboratory tests disclosed a leukopenia (2,400) with lymphocytosis (85 per cent), neutrophilia (5 per cent) and eosinophilia (5 per cent). The erythrocytes were approximately normal; thrombocytes were greatly diminished (43,000); bleeding and clotting times were greatly prolonged (thirty-two minutes and thirteen minutes, respectively). Sternal puncture showed myelocytic and metamyelocytic bone marrow conditions but no damage to the megakaryocytes. Hematuria was massive with a 9 per thousand albumin in the erythrocytic filtrate, which on spectroscopy was seen to contain no hemoglobin. The patient was given three blood transfusions of 500 cc. at intervals of three days, daily intramuscular injections of 2 cc. of liver extract and intravenous injections of 0.5 Gm. of ascorbic acid. According to the authors a hemorrhagic diathesis of the skin and mucous membrane in conjunction with septic angina justifies the diagnosis of acute hemorrhagic purpura. The general capillary system is affected. In addition the blood and bone marrow tests show a steady reduction in thrombocytes and neutrophils and an increase in lymphocytes. High fever and painful necroses in the oral regions attend the granulocytopenic manifestations, which may be so aggravated by undue physical strain as to become outright granulocytopenia. Allergy to foods or medicaments is not an etiologic factor.

Chronic Leukemia and Polycythemia.—In connection with their study of sixteen cases of myeloblastic leukemia and of the literature, Tischendorf and Herzog discuss the diagnostic difficulties (clinical, hematologic and anatomic) inherent in the disease pictures. Acute myelosis may appear simply as a hypertrophic tonsillitis and remain unrecognized until a dental intervention activates the oral infections, resulting in high fever, anemia, enlargement of the spleen and leukocytosis. The symptomatology of the subacute form is deceptive because its manifestations are variable. Acute and subacute myeloblastic leukemia may be biologic variations of chronic leukemia. Neither the leukocytic picture nor sternal puncture furnishes an unequivocal distinction between the two types. However, the subacute form is characterized by generalized edema of the lymph nodes, whereas the acute type is localized. The authors think that acute and subacute myeloblastic leukemia may rightly be regarded as of neoplastic nature. They are in agreement with other investigators that acute myelosis represents a condition of metastasizing neoplasia that needs to be studied from this point of view. Edematous processes must be interpreted as expressing the form which the varying

degrees of blood cell maturation may assume. Like leukemias, erythremias need to be regarded as tumor growths. Polycythemia not infrequently develop into myeloid leukemias, thus disclosing close interconnection. As fibromas, fibrosarcomas and sarcomas represent different degrees of maturity of the fiber tissue, blood cells may also develop with varying maturation. In myelosis, immature cells may appear abundantly in the blood and extremely immature and pathologic myeloid cells may predominate, as is shown by the malignancy and rapid evolution of micromyeloblastic leukemias.

Morphology and Clinical Aspects of Thymus.—Weise studied the morphology of the thymus in specimens obtained from surgical interventions, from ten cases of sudden death and from eighty-nine necropsies as well as in a number of dogs. These studies suggested that the thymus is a functioning gland throughout the entire life. Weise was able to demonstrate a hitherto unobserved epithelial medullary framework typical of a gland of internal secretion. The epithelial medullary reticulum of the thymus is a secretory, holocrine, tubular gland. The secretion is carried away by the lymph and blood vessels. The smallest morphologic and functional unit of the thymic medulla is a short epithelial tube, a nearly spherical body. Groups of these "primitive bodies" are connected by a common membrane. The tubule performing the holocrine function has a limited life span and new tubules are formed probably continuously throughout life. Aged tubules are transformed into Hassal's corpuscles and as such they no longer perform an endocrine function. The thymic medulla of the dog is a tubular gland only in young animals. In aged animals it is transformed into a storage organ, which retains its basic structure; namely, a parenchyma split by tubuli which are transformed into cysts. These new observations on the structure and physiology of the thymic medulla led to a new evaluation of its function in various pathologic conditions, such as osteitis fibrosa generalisata, lymphatic leukemia, lymphogranulomatosis, hepatic cirrhosis and particularly exophthalmic goiter and myasthenia gravis. In some of these disorders the tubuli seemed to be stimulated to greater activity, whereas in others an inhibitory effect was observed. Examination of the thymus in patients with exophthalmic goiter revealed a histologic picture indicative of a myasthenic component. Observations on the thymus of patients with a severe form of myasthenia pseudoparalytica disclosed morphologic and metabolic characteristics of a hyperfunctioning gland. The interpretation of myasthenia as the result of a benign neoplasm of the thymic medulla suggests the possibility of a cure through surgical intervention. Irradiation is not promising because the thymic medulla seems to be refractory to rays. The author believes that surgical removal should be attempted in severe cases of myasthenia even though the fact that the thymus may extend far on the pericardium may render the excision difficult. Thymectomy in dogs did not cause a loss of function but was followed by hyperplasia of the lymph nodes of the organism.

Raynaud's Disease and Scleroderma.—Sunder-Plassmann and Jaeger describe the clinical and neurohistologic features of two cases of Raynaud's disease associated with scleroderma. The first patient was a woman aged 34 in whom, after all conservative therapeutic methods had failed, the right stellate and the middle cervical ganglions were resected. The disfiguring facial lesions subsided. The lesions of the hands, however, contractions and trophic ulcers, as well as attacks of pain and pallor, persisted. The trophic ulcerations disappeared follow-

ing a left sided stelletomy. The second patient, a woman of 18, had a right sided stelletomy, which failed to improve the condition. Microscopic examination of the ganglions revealed identical pathologic changes. The authors believe that in Raynaud's disease associated with scleroderma, as in Raynaud's disease alone, there exists a toxic lesion in the substance of the central and peripheral portions of the sympathetic nervous system. This toxic lesion is morphologically demonstrable. It gives rise to a peculiar condition of irritation, to a hyperergic reversion in the sympathetic nervous system, which is followed by attacks of impaired blood supply and by dystrophic changes in the tissues. The authors gained the impression that hormonal changes play an important part in view of the fact that the neurosympathetic and the endocrine systems form a single biologic unit. They stress the significance of the neurohormonal cell system, which may be regarded as a part of the sympathetic preterminal plexus and the peculiar epithelial cells which exist in the ganglions of the sympathetic trunk. Certain factors, the nature of which has still to be explained but in which neurohormonal interactions play a part, are responsible for the fact that in some cases only Raynaud's disease develops while in others it may be associated with scleroderma.

Renal Threshold of Blood Sugar and Vitamin C.—By renal threshold Stöger means that concentration of blood sugar which, when exceeded, results in glycosuria. The normal threshold value in persons of about 50 years of age averages 185 mg. per hundred cubic centimeters. The renal threshold for sugar is variable and is influenced by dietetic mistakes, complicating disease, change from ordinary insulin to insulin with retarded action, hormonal changes and psychic influences. The threshold increases with age. In diabetic patients over 50 years of age it is around 200 mg. per hundred cubic centimeters and higher. The threshold increases with the duration of diabetes mellitus, but in the course of dietetic mistakes and complicating diseases it may again decrease. Renal diabetes is characterized by a low renal threshold in the presence of a normal blood sugar value, by lack of dependence of glycosuria on the food intake and by the inefficacy of insulin. The resistance to insulin involves only the glycosuria, not the glycemia. The pathogenic relationship between the renal and true diabetes is indicated by the observation that renal diabetes is frequent in relatives of diabetic patients and that renal diabetes may develop into true diabetes mellitus. The author found that oral administration of ascorbic acid in doses of from 300 to 500 mg. daily for eight days "fixed" the threshold or rapidly increased it after it had been decreased by a tolerance test. He concludes that vitamin C acts as a biocatalyzer. He employed this action of vitamin C for therapeutic purposes in cases of renal diabetes and found that the intermittent administration of vitamin C (five days every month) produced a considerable and permanent reduction of glycosuria. He thinks that this therapy might prevent or at least retard the transformation of renal diabetes into a true diabetes mellitus.

Heart Under Influence of Digitalis.—Studies on the cardiac function of patients with circulatory defects led Meyer to a new conception which he believes to be of value for the understanding of the action of digitalis. He believes that the clinical picture of cardiac insufficiency characterized by air hunger and edema is not alone and primarily the result of reduced systolic pumping action of the heart. This widely accepted opinion is not the only possible one. Studies on the cardiac beat volume of patients with circulatory defects generally disclose a normal cardiac performance. On the basis of the

constancy of the work effort of the heart in the majority of cases with clinical signs of circulatory insufficiency the author develops a new conception of the therapeutic mechanism of the digitalis bodies. According to this conception the action of digitalis is not due to an increase in the cardiac performance but rather to a change in the internal action requirements of the cardiac musculature. This change consists in the pleonectic shifting of the volume-tension curve of the cardiac musculature. The muscle is enabled to perform its work with essentially smaller initial tensions. The diseased heart can work with reduced venous filling pressures under the influence of digitalis. The correlatively increased pressure on the venous side of the circulation decreases and thus the stasis disappears, which up until then had enabled the weakened heart to do normal work. Thus it is not the change in the performance but rather in the condition of the heart which is decisive for the improvement of the circulatory disease.
